PREFACE

ABOUT THIS MANUAL

This manual is for the 4691 Service Technician who is troubleshooting or training on the 4691 Test Fixture circuit board (also known as the Threshold Voltage Test Generator or TV Generator). This manual describes how the Threshold Voltage (TV) Test Generator works and describes where in the 4691 Service Manual to refer to adjustment and operating procedures.

Tektronix

Figure 1-1. 4691 Test Fixture.

Section 1

INTRODUCTION

The 4691 Test Fixture (Threshold Voltage or TV Generator) is designed to emulate the 4691 Interface circuit board, which it replaces during troubleshooting tests. It also provides a quick procedure to vertically align (or converge) the 4691 Color Graphics Copier's ink jet heads. Finally, the Test Fixture provides a qualitative analysis of the copier's ink jet delivery system in a graphical form.

Rotary switches enable the copier's ink jet heads (except the yellow, which is not adjustable) to be easily aligned (or converged) vertically. LEDs on the 4691 Test Fixture indicate the proper setting of the DIP switches on the 4691 Interface circuit board. In practice, the technician simply runs the convergence procedure (found in Section 8 of the 4691 Service Manual) and adjusts the three DELAY rotary switches on the 4691 Test Fixture until proper adjustment is obtained. Then, the DIP switches on the 4691 Interface circuit board are set to match the LEDs on the 4691 Test Fixture.

Ink jet head analysis is obtained by sweeping the ink jet head driver voltage with an increasing voltage at discrete frequencies, about 40 Hertz apart, beginning at five KHz and continuing to 40 KHz. This "spectrum analysis" of each ink jet head, which is printed on paper, can be analyzed to detect clogs, air bubbles, lack of air pressure or ink, etc.

Section 2

THEORY OF OPERATION

INTRODUCTION

The Threshold Voltage Test is designed to diagnose the cause of ink jet head problems.

The Threshold Voltage Test performs a "spectrum analysis" of the copier's ink system. The fundamental principle of the Threshold Voltage Test is that it requires a higher ink jet head voltage to cause printing when the resonance frequency of the particle or air bubble in the ink system is reached. The ink jet heads are designed so that for each printing signal frequency, a certain minimum drive voltage is required to cause the ink jet head to squirt a drop of ink. This minimum drive voltage is the "threshold voltage." Normally, there is a linear, but gradually increasing, relationship between the threshold voltage and the printing signal frequency. So, if we can graph the printing voltage amplitude on the vertical axis and the frequency of the printing signal on the horizontal axis, a relatively smooth, linear printing pattern should result as shown by the lower portion of the printing pattern shown in Figure 2-1. However, if a foreign particle or air bubble is in the ink system, the particle or bubble will absorb energy from the ink jet head drive voltage. The maximum energy absorption occurs at the resonance frequency of the particle or bubble. Studies have shown that nearly all air bubbles and foreign particles resonate between 5 KHz and 40 KHz. Figure 2-2 shows an example of an air bubble in the ink system. Notice the "notch" at approximately 13.75 KHz. This air bubble has absorbed enough energy from the drive voltage so that printing does not occur until the ink jet head drive voltage reaches nearly 130 volts when the printing signal is around 13.75 KHz. Without the air bubble, that particular ink jet head would have required only 60 or 70 volts to print at that frequency. Remember, that each ink jet head requires a slightly different threshold voltage for each frequency (different signature), but the principle is still the same. Also, each air bubble will resonate at a different frequency, so do not attempt to categorize problems on the basis of frequency and/or voltage measurements.

SECTION 2 THEORY OF OPERATION

Figure 2-1 shows the other parameters of the Threshold Voltage Test pattern. The printing signal is swept in 40 Hz steps, starting at 5 KHz and for each 40 Hz step, the ink jet head drive voltage is swept (increased) from 0 (at the bottom of the pattern, shown by the horizontal line) to a pre-determined upper limit. For example, notice that on Figure 2-1 at 20 KHz, the upper ink jet head drive voltage is set at 180 volts. Printing, however, started at about 90 to 100 volts at that frequency. Also notice that when the printing frequency reached 6.25 KHz, the upper limit voltage was increased slightly, causing a "stair-step" effect shown in Figure 2-1. Each stair-step indicates a 1.25 KHz range. Finally, upper limit voltages are set low at the lower frequencies to prevent damage to the ink jet heads.

It must be realized that an infinite number of test pattern variations might occur depending upon the size and location of a foreign particle or air bubble. Therefore, some interpretation of the test pattern might be necessary in some cases. However, generally you are looking for a straight threshold voltage pattern (lower portion of the printing pattern shown in Figure 2).

Refer to Appendix H of the 4691 Service Manual for interpretation of the Threshold Voltage Test Patterns.

SECTION 2 THEORY OF OPERATION

CIRCUIT DESCRIPTIONS

GENERAL

Figure 2-3 shows a block diagram for the 4691 Test Fixture. Also, refer to the Schematics in Section 6 when reading this description.

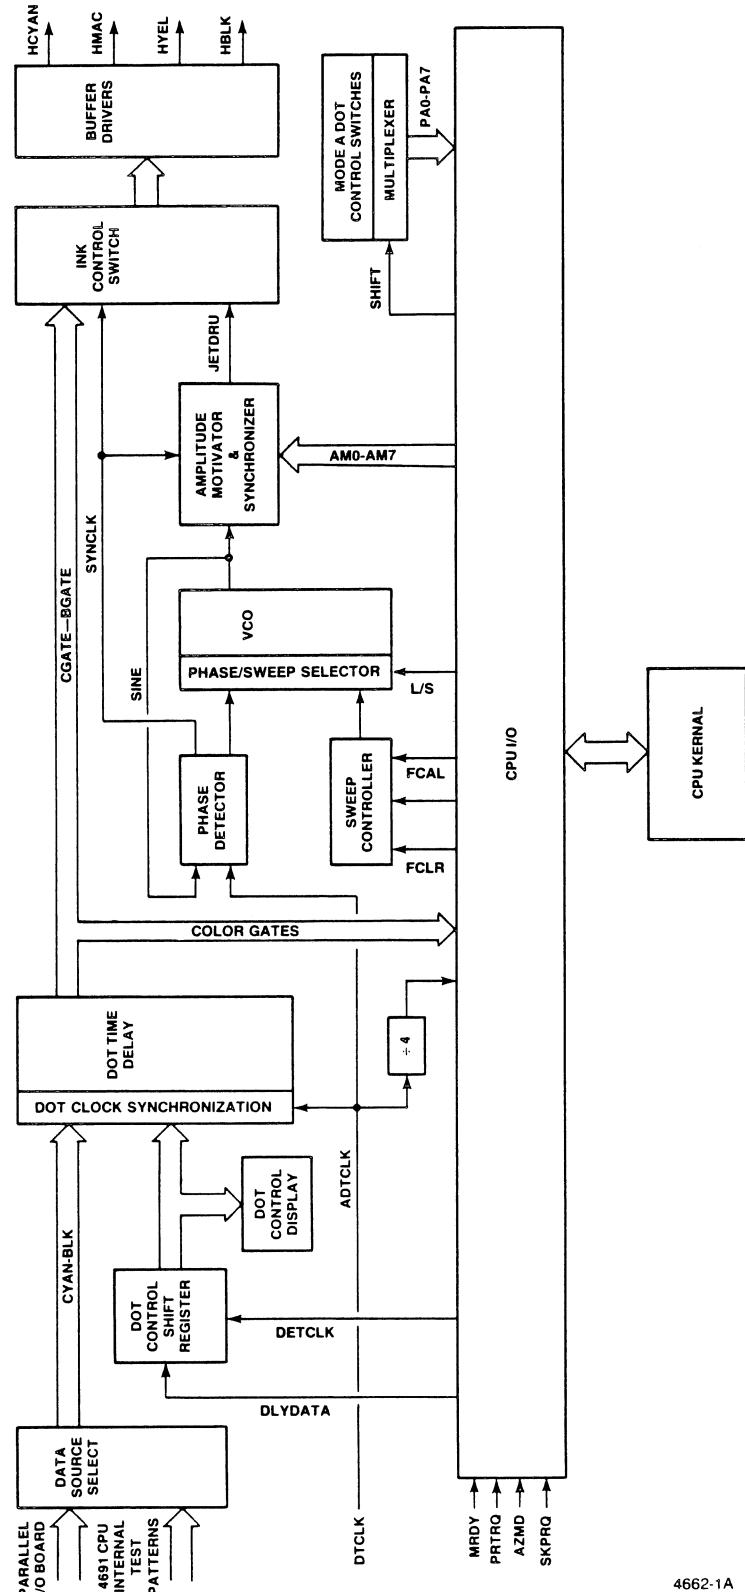

Data Source Select allows image information to be furnished from either the 4691 CPU circuit board or the Parallel Interface circuit board. A combination of the rear panel TEST/OPERATE and the TEST PATTERN SELECT/START switches determine the data source through the Data Source Select. The selected image information is then sent to the Dot Time Delay where each color is delayed by two values. The first value is a fixed amount which allows for the offset of the heads with respect to the circumference and the second value is a variable amount which is controllable by the Dot Control Shift Register, which allows for slight misalignment of the heads. The Dot Control Shift Register is controlled by the DOT CONTROL switches which are debounced and modified under software control by the processor.

From the Dot Time Delay, the color gates are sent to the Ink Control Switch where the analog JETDRV signal is gated to the BUFFER/DRIVERS. From there the color signal is sent to the Ink Jet Head Driver circuit board and the ink jet heads. The analog JETDRV signal is a rough sinewave which is amplitude controlled by the processor and is derived from the Voltage Controlled Oscillator (VCO). Control input for the VCO comes from either a phase detector which locks the VCO output at 20 KHz during normal operation or from the Sweep Controller which is under computer control and used during CAL and TEST Modes.

DATA SOURCE SELECT

The Data Source Select selects color signals from either the Parallel Interface or the CPU internal test patterns. The multiplexor is controlled by a combination of the address lines (bus).

SECTION 2
THEORY OF OPERATION

4662-1A

Figure 2-3. 4691 Test Fixture Block Diagram.

SECTION 2 THEORY OF OPERATION

DOT TIME DELAY

The Dot Time Delay actually consists of four separate circuits - one for each color (yellow, magenta, cyan, and black). The first stage of each circuit provides synchronization with DTCLK (data clock). Then the remainder of each circuit is a fixed time delay whose value depends upon the physical location of the ink jet heads with respect to the drum at index time. The yellow ink jet head is the reference ink jet head and its delay time was set at zero (no delay). The outputs of each of the other three Dot Time Delays are determined by variable length shift registers which are set by the CPU Processor. This allows the ink jet heads to be electrically converged in the vertical direction.

DOT CONTROL SHIFT REGISTER

The Dot Control Shift Register accepts clocked serial dot delay information (DLYDATA) from the CPU Kernal (via the CPU I/O) and presents it in parallel format to both the Dot Control Display LEDs, which provide the operator with a visual indication of the Dot Control Switches and the Dot Time Delay (described earlier).

DOT CONTROL DISPLAY

The Dot Control Display consists of 15 LEDs which show the delay for each color except yellow. The operator uses these LEDs to set the DOT CONTROL switches on the 4691 Interface circuit board (removed during test and adjustment).

PHASE DETECTOR

The Phase Detector compares the VCO output frequency (20 KHz) to the DTCLK signal (actually ADTCLK-1). If the two signals differ, a dc output correction voltage corrects the VCO. In addition, the Phase Detector produces a squarewave reference frequency which is used by both the Amplitude Modulator and Synchronizer and the Ink Control Switch to synchronize color information to the derived clock (JETDRV).

SWEEP CONTROLLER

The Sweep Controller consists of a counter controlled by the CPU Kernal and a digital-to-analog (D-to-A) converter. The Sweep Controller generates a dc voltage (DAC) for the VCO. The D-to-A converter can be cleared, incremented, or forced to 20 KHz under control of the CPU Kernal.

SECTION 2 THEORY OF OPERATION

VOLTAGE CONTROLLED OSCILLATOR (VCO)

The VCO generates a constant amplitude sinewave signal, which will be amplitude modulated and applied to the ink jet heads. The output frequency of the VCO is determined by a control voltage from either the Phase Detector or the Sweep Controller. An input multiplexor (Phase/Sweep Selector) under CPU Kernal control determines which control signal is applied to the VCO.

AMPLITUDE MODULATOR AND SYNCHRONIZER

The VCO sinewave signal is modulated under CPU Kernal control to produce the signal JETDRV. Amplitude information for the converter is changed only during minus zero crossings by SYNCLK. This guarantees that only integral sinewaves are generated at the JETDRV test point.

INK CONTROL SWITCHES

These switches gate the JETDRV signal to the Buffers/Drivers as required by the color gate signals to produce ink delivery in the desired pattern.

BUFFERS/DRIVERS

The Buffers/Drivers are unity gain amplifiers for the ink jet head drive signals and provide circuit board isolation and drive capability.

MODE AND DOT CONTROL SWITCHES

The Mode and Dot Control Switches circuit block consists of the ON, TV, CONVERGENCE, CALIBRATION, and the three DELAY switches. The switch data is multiplexed and transmitted to the CPU Kernal. The multiplexor is controlled by SHIFT (Pin 10 of U271).

CPU I/O

The CPU I/O consists of a PIA containing two eight-bit input ports and a VIA containing two eight-bit output ports. The CPU I/O permits the CPU Kernal to communicate with various chips within the 4691 Test Fixture.

SECTION 2
THEORY OF OPERATION

CPU KERNEL

The CPU Kernal consists of a 6504 NMOS microprocessor, 128 bytes of RAM, and 2K bytes of ROM.

4691 Test Fixture Firmware Description/Operation

Mainline. Circuit operation begins when the CPU circuit board releases the RESET signal to 4691 Test Fixture CPU Kernal. The CPU Kernal turns off all interrupts, clears out Decimal Mode, and sets up the stack to the top of RAM (0OFF hex). It then proceeds to set the I/O ports and performs a RAM check. If a RAM should fail, a binary one will be displayed in the BLACK DOT DELAY LEDs. When the RAM checks all right, a ROM check is performed. If a ROM fails, a binary two is displayed in the BLACK DOT DELAY LEDs.

After the initial self-tests have been performed, the CPU Kernal sets up the variables necessary for operation. This includes setting the frequency of the D/A to zero and enabling the interrupts. The CPU Kernal begins a circular scan of flags generated by the interrupt routine. The first item in the scan is a check of the main INDICATOR LED. Next, a check is made of the various switches to see if a particular test has been operator-selected. If a test is selected, the routine jumps to the test routine. When the test is completed, the scan begins again.

Calibrate Mode. In the Calibrate Mode, the CPU Kernal clears the frequency control D/A and forces the high order bit to a one. This causes the D/A to assert its mid-range value. The LOCK/SWEEP control line is set to the sweep position, which disables the phase-locked control of the dot clock and substitutes the digital-to-analog sweep controller. The flash rate of the INDICATOR LED is quadrupled to indicate that Flash Mode is active, and the multiplying DAC is set to mid-range, which is the calibration amplitude. The CPU Kernal waits for a switch to be pressed and then exits to the circular scanner.

SECTION 2 THEORY OF OPERATION

TV Test Mode. When the TV Test Mode is indicated, the CPU Kernal halves the flash rate for the INDICATOR LED to indicate that TV Test has been selected. The CPU Kernal checks that the 4691 bus signals are valid to perform a TV Test (i.e. MRDY is low and PRTRQ is high (see Figure 2-4)). Next, a variable called TESTFLG is set to zero and any pending skip request interrupts are cleared. The skip request interrupt is then enabled. The CPU Kernal waits for PRTRQ from the 4691 bus to go low indicating that the operator has requested a test pattern. If the variable TESTFLG has been set to 80 by the interrupt routine, the Parallel Interface circuit board generates the pattern needed for the TV Test. If not, the routine turns off the INDICATOR LED and waits for the current image to end and return to the circular scanner.

NOTE

The Parallel Interface circuit board generates a signal on the SKIPRQ line just prior to PRTRQ going low which indicates to the 4691 Test Fixture that either the pattern for the TV Test or the Alignment Test is about to be generated. This interlocks the Parallel Interface circuit board and the 4691 Test Fixture circuit board together.

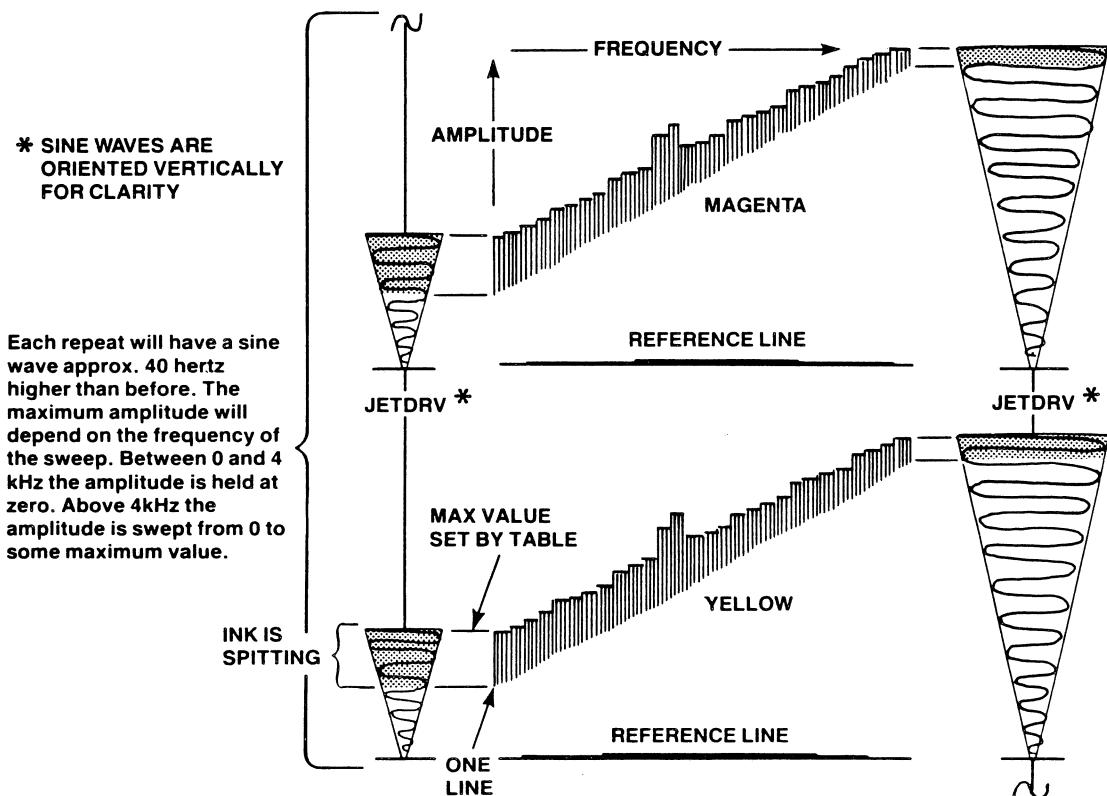

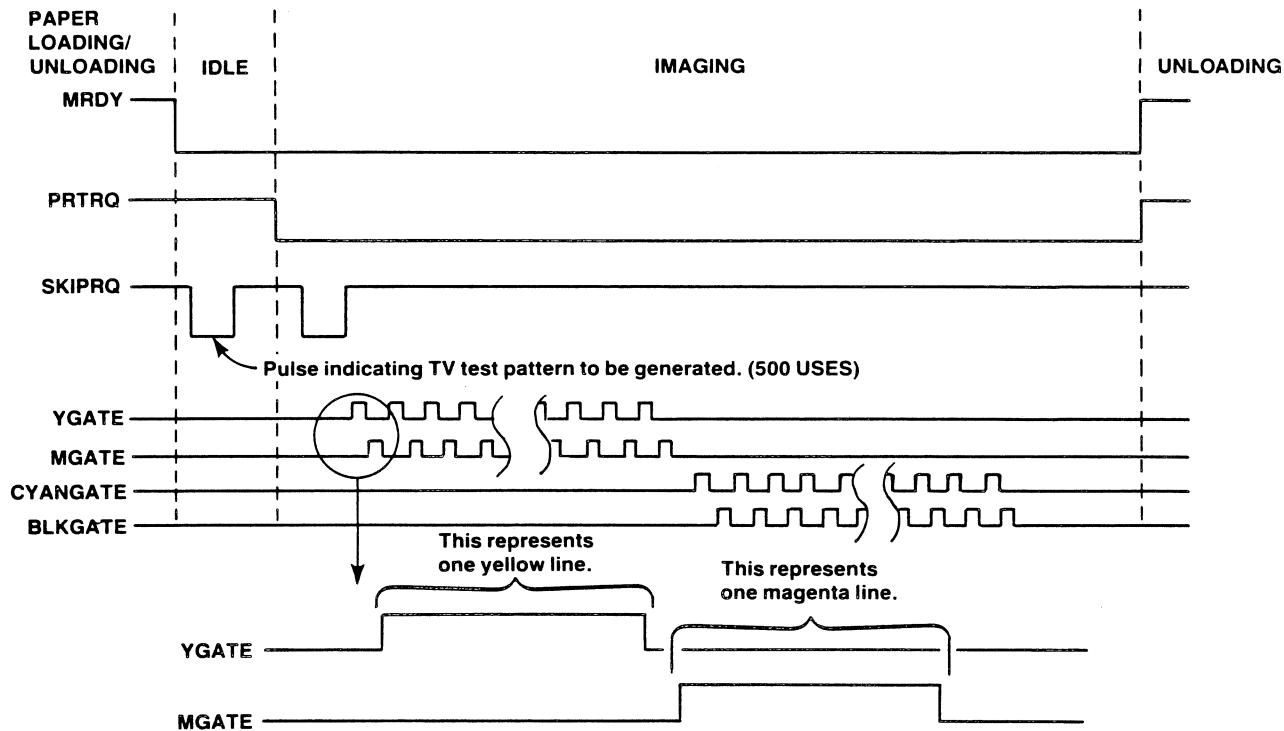

If we assume that the correct signals for the TV Test have been received, the CPU Kernal will turn off the timer interrupt, turn on the INDICATOR LED, and turn on the sweep control. The CPU Kernal checks the paper size status line to set up variables for either A or B size paper. Finally, the PRTRQ interrupt is enabled to catch a positive going edge (end of image) which is used to terminate the routine if the front panel STOP COPY switch is pressed or if the 4691 copier should have some other failure.

The 4691 Test Fixture then begins to generate the image by setting a mask to look for the yellow gate and setting the amplitude to zero. As soon as the yellow gate is detected, the maximum amplitude value allowed for the given frequency is output as a reference line. The CPU Kernal waits for the divided by four clock to toggle and when it does, the CPU Kernal outputs a value of zero. Each subsequent divided by four clock will cause the amplitude to be increased according to a "look-up" table in ROM. When the maximum amplitude is reached, the output will be held at zero. The maximum value is variable depending on the frequency, and is also a method of distinguishing frequency steps.

SECTION 2
THEORY OF OPERATION

When the maximum value is reached, the color mask is set for the magenta gate, and the process is repeated until the proper number of lines have been generated. The process then repeats again with the cyan and black gates substituted for the yellow and magenta gates.

SECTION 2
THEORY OF OPERATION

4662-2

Figure 2-4. 4691 Test Fixture Timing Diagram.

SECTION 2 THEORY OF OPERATION

Background Interrupt Routine. The background interrupt routine performs several functions, all under the direction of the mainline program (described earlier). The first thing to be checked is the skip request interrupt. If the skip request is detected, the background interrupt routine begins looking for the SKIPRQ line to return high while counting the time the line is low. The time the line is low is used to determine if a TV Test pattern is going to be generated and the value of TESTFLG is set accordingly.

Next, the PRTRQ (print request) interrupt is checked to see if the print has been aborted. If the print has been aborted, a complete power-up restart is started. The timer interrupt is checked to see if it is time to toggle the INDICATOR LED and, finally, the switches are scanned to see if they have been operator-changed. If the DELAY switches have been changed, the interrupt routine debounces and processes the data and updates the delays and LEDs accordingly. If the CONTROL switches have been changed, the routine debounces them and presents the data to the circular scanner to be acted upon.

Section 3

REPLACEABLE ELECTRICAL PARTS

Replacement parts are available from or through your local Tektronix, Inc. Field Office or representative.

Changes to Tektronix instruments are sometimes made to accommodate improved components as they become available, and to give you the benefit of the latest circuit improvements developed in our engineering department. It is therefore important, when ordering parts, to include the following information in your order: Part number, instrument type or number, serial number, and modification number if applicable.

If a part you have ordered has been replaced with a new or improved part, your local Tektronix, Inc. Field Office or representative will contact you concerning any change in part number.

Change information, if any, is located at the rear of this manual.

LIST OF ASSEMBLIES

A list of assemblies can be found at the beginning of the Electrical Parts List. The assemblies are listed in numerical order. When the complete component number of a part is known, this list will identify the assembly in which the part is located.

CROSS INDEX-MFR. CODE NUMBER TO MANUFACTURER

The Mfr. Code Number to Manufacturer index for the Electrical Parts List is located immediately after this page. The Cross Index provides codes, names and addresses of manufacturers of components listed in the Electrical Parts List.

ABBREVIATIONS

Abbreviations conform to American National Standard Y1.1

COMPONENT NUMBER (column one of the
Electrical Parts List)

A numbering method has been used to identify assemblies, subassemblies and parts. Examples of this numbering method and typical expansions are illustrated by the following:

Example a. The assembly number A23R1234 is broken down as follows:

- component number**: A23
- circuit number**: R1234

The assembly number A23R1234 is shown at the top. Below it, a bracket labeled "component number" covers the segment "A23". Another bracket labeled "circuit number" covers the segment "R1234". At the bottom, a bracket labeled "Assembly number" covers the entire assembly number, and another bracket labeled "Circuit number" covers the entire assembly number.

Read: Resistor 1234 of Assembly 23

The diagram illustrates the hierarchical breakdown of an assembly number. At the top, the assembly number **A23A2R1234** is shown. Above it, a bracket labeled **component number** covers the first two digits, **A23**. Below this, another bracket labeled **Subassembly number** covers the next two digits, **A2**. At the bottom, a bracket labeled **Circuit number** covers the final four digits, **R1234**.

Read: Resistor 1234 of Subassembly 2 of Assembly 23

Only the circuit number will appear on the diagrams and circuit board illustrations. Each diagram and circuit board illustration is clearly marked with the assembly number. Assembly numbers are also marked on the mechanical exploded views located in the Mechanical Parts List. The component number is obtained by adding the assembly number prefix to the circuit number.

The Electrical Parts List is divided and arranged by assemblies in numerical sequence (e.g., assembly A1 with its subassemblies and parts, precedes assembly A2 with its subassemblies and parts).

Chassis-mounted parts have no assembly number prefix and are located at the end of the Electrical Parts List.

**TEKTRONIX PART NO. (column two of the
Electrical Parts List)**

Indicates part number to be used when ordering replacement part from Tektronix.

**SERIAL/MODEL NO. (columns three and four
of the Electrical Parts List)**

Column three (3) indicates the serial number at which the part was first used. Column four (4) indicates the serial number at which the part was removed. No serial number entered indicates part is good for all serial numbers.

**NAME & DESCRIPTION (column five of the
Electrical Parts List)**

In the Parts List, an Item Name is separated from the description by a colon (:). Because of space limitations, an Item Name may sometimes appear as incomplete. For further Item Name identification, the U.S. Federal Cataloging Handbook H6-1 can be utilized where possible.

MFR. CODE (column six of the Electrical Parts List)

Indicates the code number of the actual manufacturer of the part. (Code to name and address cross reference can be found immediately after this page.)

**MFR. PART NUMBER (column seven of the
Electrical Parts List)**

Indicates actual manufacturers part number.

REPLACEABLE MECHANICAL PARTS

PARTS ORDERING INFORMATION

Replacement parts are available from or through your local Tektronix, Inc. Field Office or representative.

Changes to Tektronix instruments are sometimes made to accommodate improved components as they become available, and to give you the benefit of the latest circuit improvements developed in our engineering department. It is therefore important, when ordering parts, to include the following information in your order: Part number, instrument type or number, serial number, and modification number if applicable.

If a part you have ordered has been replaced with a new or improved part, your local Tektronix, Inc. Field Office or representative will contact you concerning any change in part number.

Change information, if any, is located at the rear of this manual.

SPECIAL NOTES AND SYMBOLS

X000 Part first added at this serial number

00X Part removed after this serial number

FIGURE AND INDEX NUMBERS

Items in this section are referenced by figure and index numbers to the illustrations.

INDENTATION SYSTEM

This mechanical parts list is indented to indicate item relationships. Following is an example of the indentation system used in the description column.

1 2 3 4 5	Name & Description
	Assembly and/or Component
	Attaching parts for Assembly and/or Component

	Detail Part of Assembly and/or Component
	Attaching parts for Detail Part

	Parts of Detail Part
	Attaching parts for Parts of Detail Part

Attaching Parts always appear in the same indentation as the item it mounts, while the detail parts are indented to the right. Indented items are part of, and included with, the next higher indentation. The separation symbol ----- indicates the end of attaching parts.

Attaching parts must be purchased separately, unless otherwise specified.

ITEM NAME

In the Parts List, an Item Name is separated from the description by a colon (:). Because of space limitations, an Item Name may sometimes appear as incomplete. For further Item Name identification, the U.S. Federal Cataloging Handbook H-6-1 can be utilized where possible.

FIG. 1 EXPLODED VIEW

4691 TEST FIXTURE SERVICE

Section 4

CALIBRATING THE 4691 TEST FIXTURE

1. Ensure that the copier's POWER switch is OFF.
2. Remove the Interface circuit board from the copier's card cage (see Section 7 in the 4691 Service Manual for instructions on removing this circuit board).
3. Install the Extender circuit board in the slot formerly occupied by the Interface circuit board.
4. Install the 4691 Test Fixture into the Extender circuit board.
5. Ensure that the Test Fixture's ON/OFF switch is in the OFF (out) position (see Figure 1-1) and the MAG, CYAN, and BLK DELAY switches are set to zero.
6. Turn the copier's POWER switch ON. The test fixture will now perform a RAM and ROM test. If the INDICATOR LED fails to light and the BLACK DELAY LEDs indicate the number 1 (in binary), RAM fail has occurred. If the BLACK DELAY LEDs indicate a number 2 (in binary), a ROM failure has occurred.
7. Check that the INDICATOR LED is flashing at a once per second rate. This indicates that the test fixture is in an idle mode scanning the test fixture switches. The MAG, CYAN, and BLK DELAY LEDs indicate the print delay for each color (refer to the Convergence Procedure in Section 8 of the 4691 Service Manual).
8. Turn the MAG, CYAN, and BLK DELAY rotary switches and notice that the MAG, CYAN, and BLK DELAY LEDs follow the switches.
9. Push in the CALIBRATION switch and the ON switch. The test fixture is now in the CAL Mode and the INDICATOR LED should flash at a four times per second rate.
10. Connect an oscilloscope (1V/Div, 10 uS/Div) between SYNCLK (TP553) and ground (TP655, see Figure 1-1).
11. Adjust R731 (SYM, or symmetry) to obtain a square-wave at TP553 (SYNCLK).
12. Adjust R828 (FREQ, or frequency) to obtain a period of 50 uS plus or minus 1 uS.

SECTION 4 ADJUSTMENT PROCEDURES

13. Move the signal lead of the oscilloscope to TP745 (SINE) and notice that the sinewave has little distortion.
14. Move the oscilloscope's signal lead to TP651 (JETDRV).
15. Adjust R851 (AMPLITUDE) for a p-p voltage of 3.30 volts (1.0 volt rms).
16. Push the ON/OFF switch to release it to the out (OFF) position.

NOTE

The 4691 Test Fixture is now adjusted. If the Threshold Voltage Test is desired, proceed to Step 9 in Section 5 of this manual.

17. Turn the copier's POWER switch OFF.
18. Remove the 4691 Test Fixture and the Extender circuit board and replace the Interface circuit board (removed in Step 2).

This completes the adjustment of the 4691 Test Fixture.

Section 5

USING THE TEST FIXTURE TO CALIBRATE THE COPIER

1. Ensure that the copier's POWER switch is OFF.
2. Remove the Interface circuit board from the copier's card cage (see Section 7 in the 4691 Service Manual for instructions on removing this circuit board).
3. Install the Extender circuit board in the slot formerly occupied by the Interface circuit board.
4. Install the 4691 Test Fixture into the Extender circuit board.
5. Ensure that the Test Fixture's ON/OFF switch is in the OFF (out) position (see Figure 1-1) and the MAG, CYAN, and BLK DELAY switches are set to zero.
6. Turn the copier's POWER switch ON. The test fixture will now perform a RAM and ROM test. If the INDICATOR LED fails to light and the BLACK DELAY LEDs indicate the number 1 (in binary), RAM fail has occurred. If the BLACK DELAY LEDs indicate a number 2 (in binary), a ROM failure has occurred.
7. Check that the INDICATOR LED is flashing at a once per second rate. This indicates that the test fixture is in an idle mode scanning the test fixture switches. The MAG, CYAN, and BLK DELAY LEDs indicate the print delay for each color (refer to the Convergence Procedure in Section 8 of the 4691 Service Manual).
8. Push the ON/OFF switch to release it to the out (OFF) position.
9. Push in the TV switch and then the ON switch. Observe that the INDICATOR LED flashes at a once per two second rate. This indicates that the test fixture is waiting for the start of the Threshold Voltage Test pattern.
10. Set the copier's rotary five-position TEST PATTERN SELECT switch to three and press the TEST START switch. The INDICATOR LED will turn on steady when the copier starts printing the Threshold Voltage pattern. The printing takes about two minutes on A size paper or about four minutes on B size paper. If the INDICATOR LED fails to light, the wrong test pattern has been selected.

SECTION 5
OPERATING PROCEDURES

NOTE

Once the Threshold Voltage test pattern has started, the test fixture switches are deactivated. To abort the test, press the copier's front panel STOP COPY switch.

11. Refer to Appendix H of the 4691 Service Manual for interpretation of the Threshold Voltage test pattern.
12. After the test pattern has been printed and you wish to restore the copier to normal operation, push the ON/OFF switch to release it to the out (OFF) position.
13. Turn the copier's POWER switch OFF.
18. Remove the 4691 Test Fixture and the Extender circuit board and replace the Interface circuit board (removed in Step 2).

This completes the operation of the 4691 Test Fixture.

Section 6

SCHEMATICS

Symbols and Reference Designators

Electrical components shown on the diagrams are in the following units unless noted otherwise:

Capacitors = Values one or greater are in picofarads (pF).

Values less than one are in microfarads (μ F).

Resistors = Ohms (Ω).

Graphic symbols and class designation letters are based on ANSI Standard Y32.2-1975.

Logic symbology is based on ANSI Y32.14-1973 in terms of positive logic. Logic symbols depict the logic function performed and may differ from the manufacturer's data.

Abbreviations are based on ANSI Y1.1-1972. Other ANSI standards that are used in the preparation of diagrams by Tektronix, Inc., are:

Y14.15, 1966 Drafting Practices.

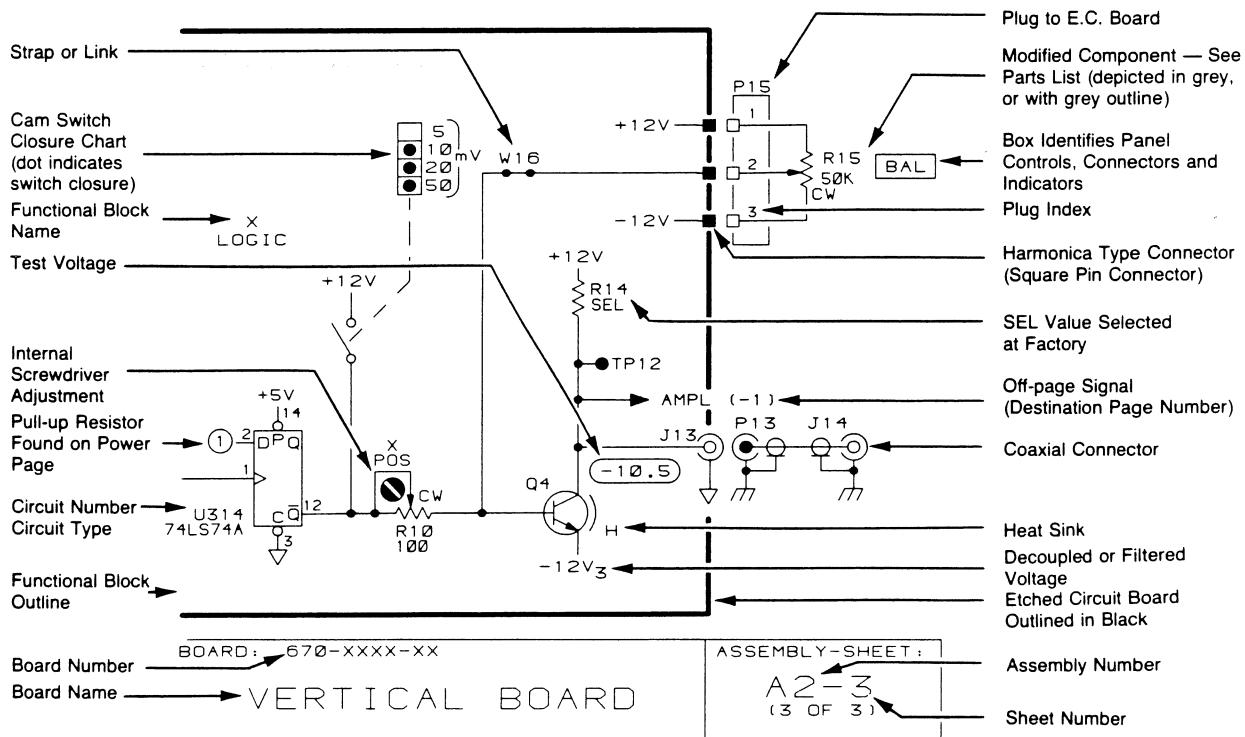

Y14.2, 1973 Line Conventions and Lettering.

Y10.5, 1968 Letter Symbols for Quantities Used in Electrical Science and Electrical Engineering.

The following prefix letters are used as reference designators to identify components or assemblies on the diagrams.

A	Assembly, separable or repairable (circuit board, etc.)	H	Heat dissipating device (heat sink, heat radiator, etc.)	S	Switch or contactor
AT	Attenuator, fixed or variable	HR	Heater	T	Transformer
B	Motor	HY	Hybrid circuit	TC	Thermocouple
BT	Battery	J	Connector, stationary portion	TP	Test point
C	Capacitor, fixed or variable	K	Relay	U	Assembly, inseparable or non-repairable (integrated circuit, etc.)
CB	Circuit breaker	L	Inductor, fixed or variable	V	Electron tube
CR	Diode, signal or rectifier	M	Meter	VR	Voltage regulator (zener diode, etc.)
DL	Delay line	P	Connector, movable portion	W	Wirestrap or cable
DS	Indicating device (lamp)	Q	Transistor or silicon-controlled rectifier	Y	Crystal
E	Spark Gap, Ferrite bead	R	Resistor, fixed or variable	Z	Phase shifter
F	Fuse	RT	Thermistor		
FL	Filter				

The following special symbols may appear on the diagrams:

SCHEMATICS

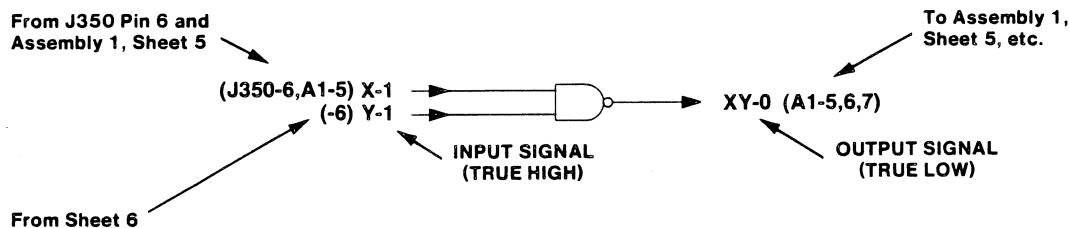

1. True High and True Low Signals

Signal names on the schematics are followed by -1 or a -0. A TRUE HIGH signal is indicated by -1, and a TRUE LOW signal is indicated by -0.

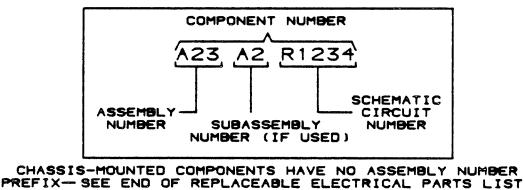

SIGNAL -1 = TRUE HIGH
SIGNAL -0 = TRUE LOW

2. Cross-References

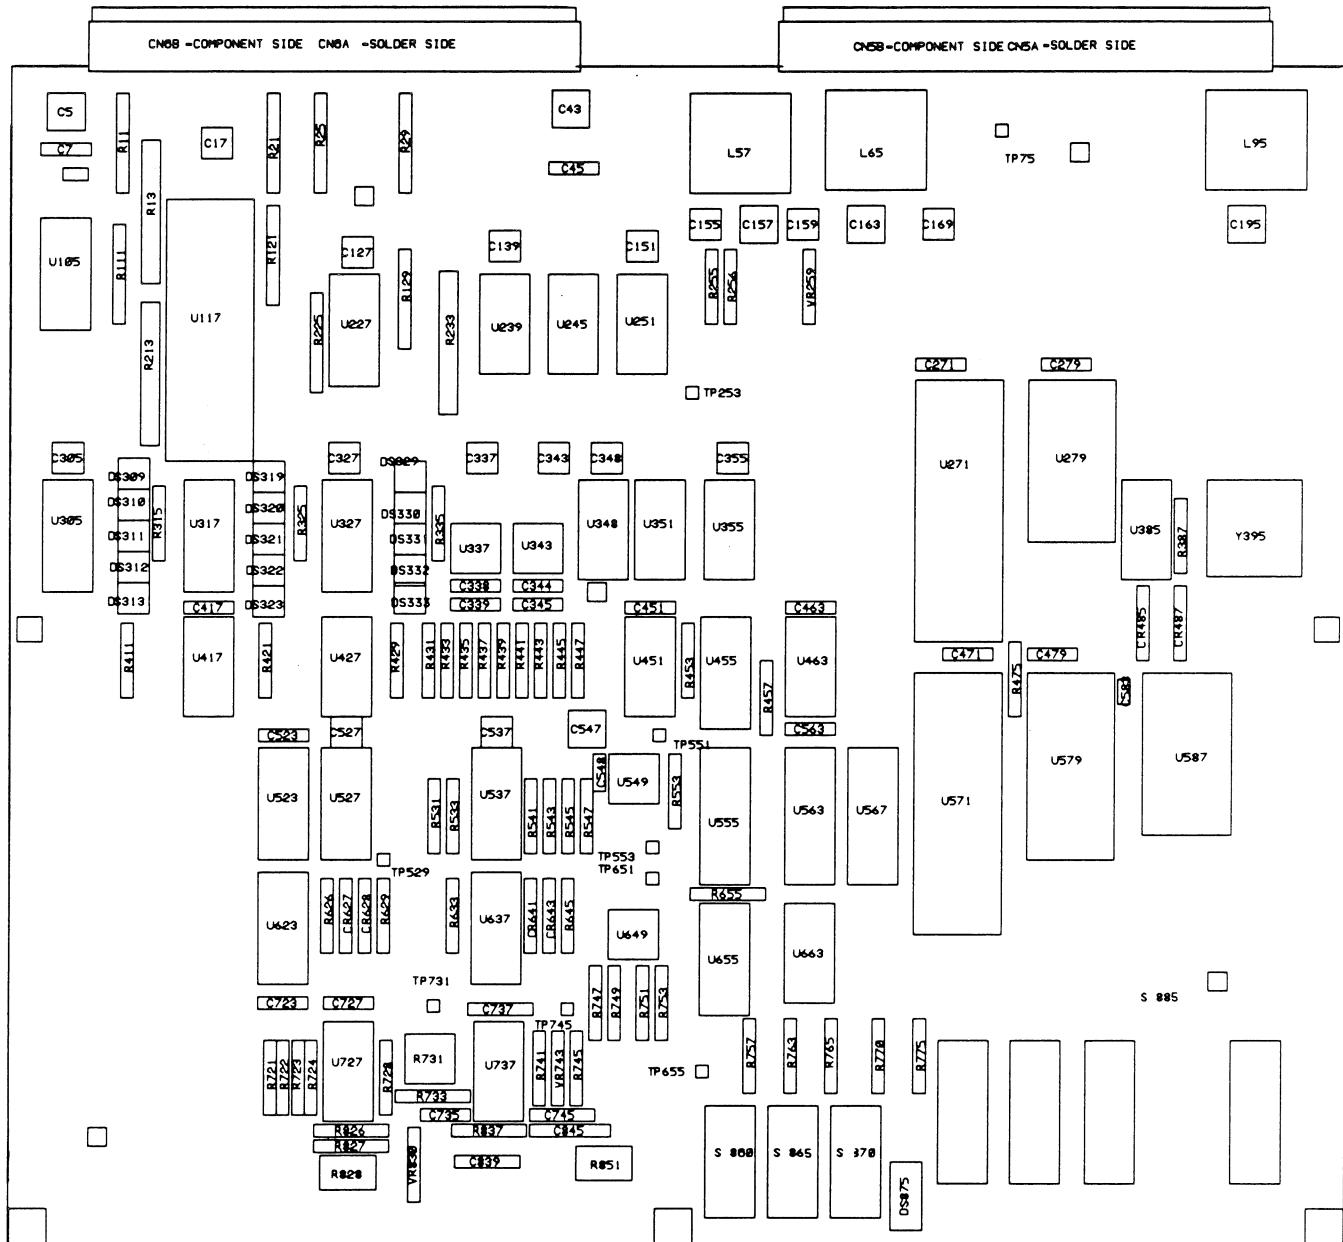

Schematic cross-references (from/to information) are included on the schematics. The "from" reference only indicates the signal "source," and the "to" reference lists all loads where the signal is used. All from/to information will be enclosed in parentheses.

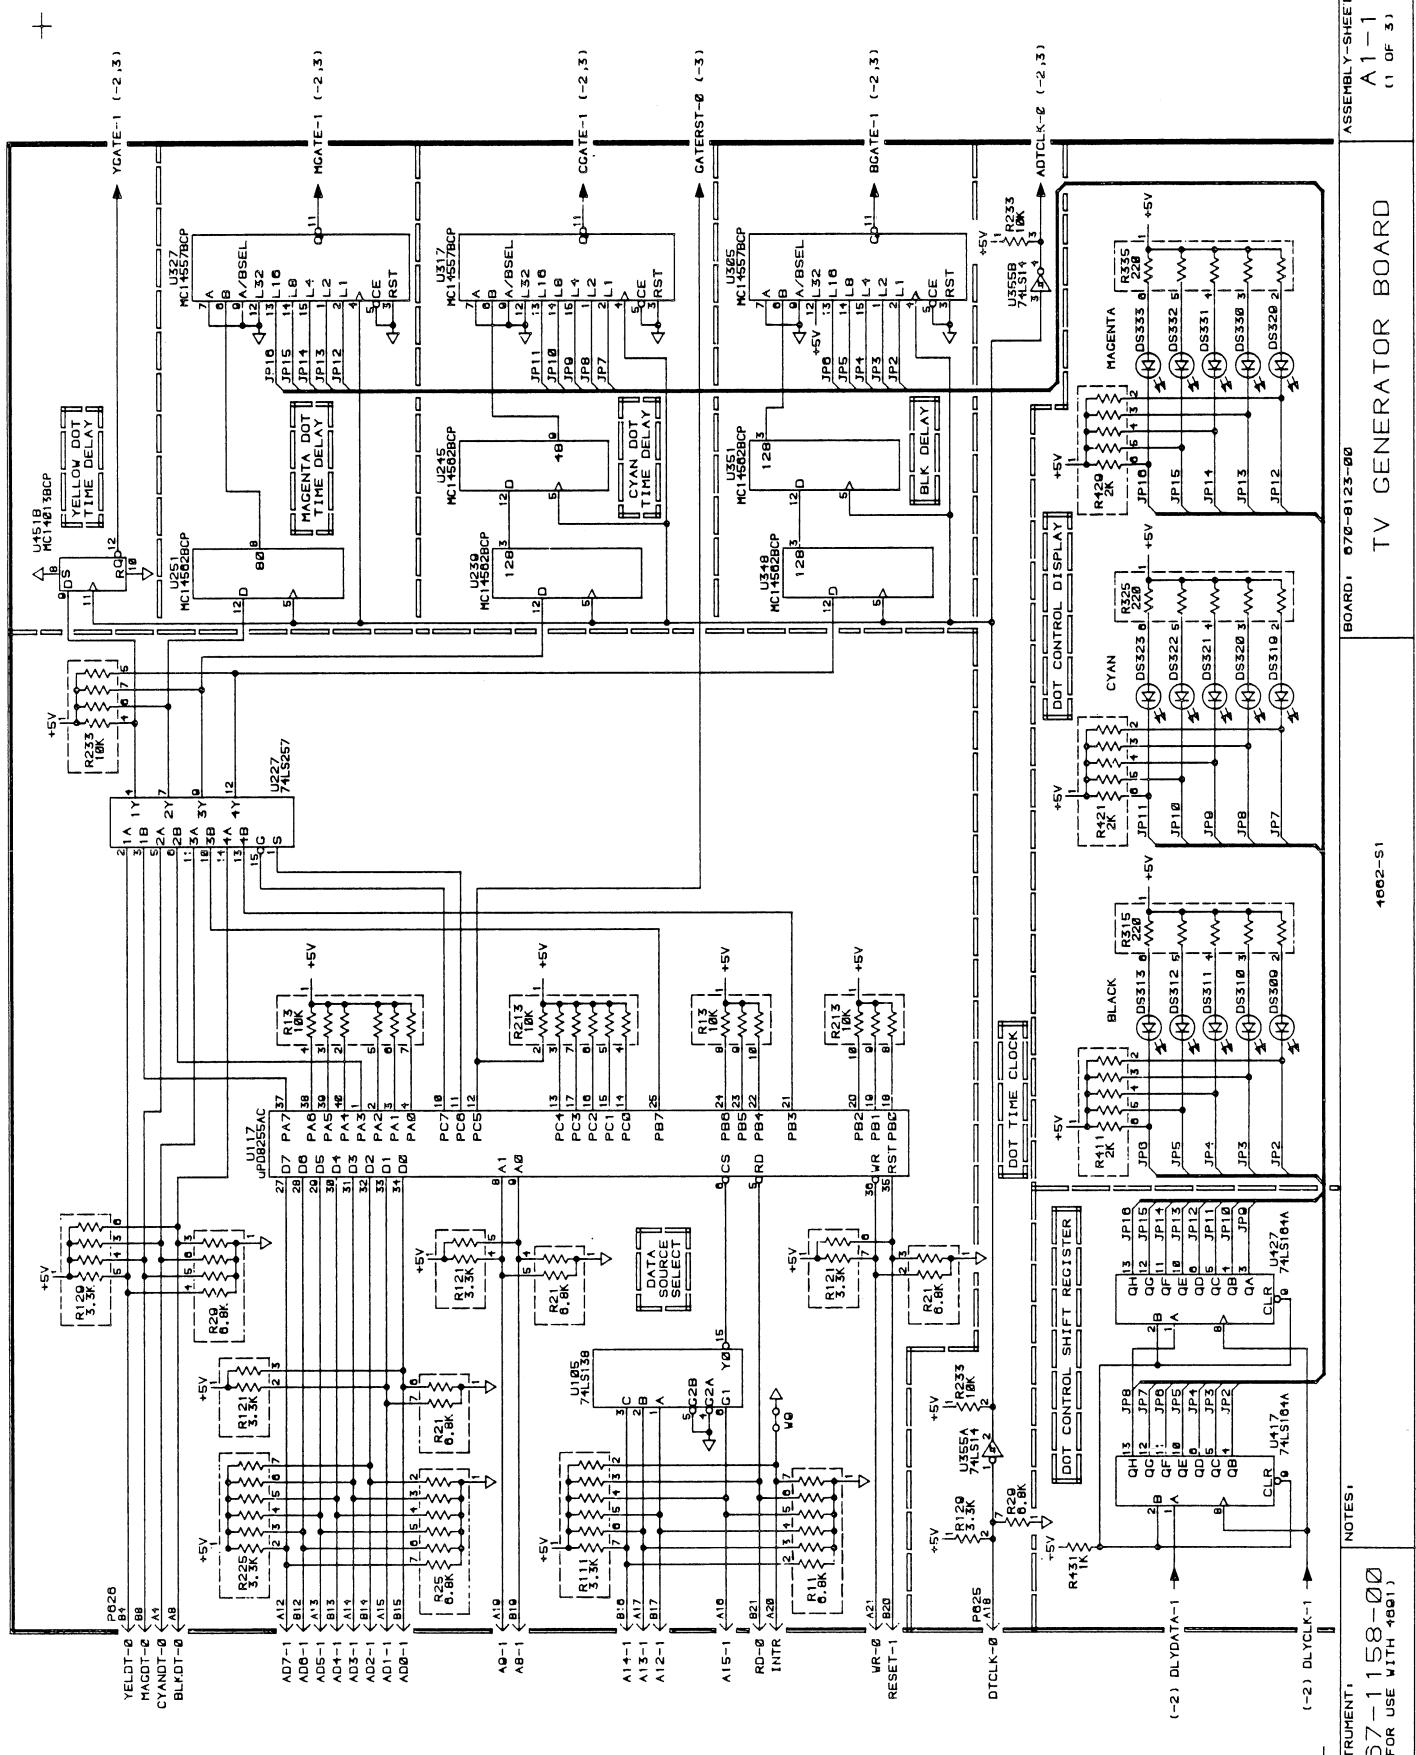

3. Component Number Example
