CHANGE INFORMATION

Abbreviations and symbols used in this manual are based on or taken directly from IEEE Standard 260 "Standard Symbols for Units", MIL-STD-12B and other standards of the electronics industry. Change information, if any, is located at the rear of this manual.

Fig. 1-1. 7D14 Digital Counter Plug-In Unit,

# SECTION 1 SPECIFICATION 

Change information, if any, affecting this section will be found at the rear of this manual.

## Introduction

The 7D 14 Digital Counter plug-in unit is designed for use with Tektronix 7000-series Oscilloscopes equipped with readout system. The 7D14 uses the readout system to display an eight-digit readout on the CRT of the associated oscilloscope. The 7D14 will measure frequency from 0 to 525 megahertz, frequency ratio from 0 to $10^{5}: 1$ and totalize (count number of events) from 0 to $10^{8}$. The 7D 14 features counting capability to 525 megahertz without prescaling, input impedance of 50 ohms or 1 megohm, blanking of all zeros to the left of the most significant digit,
trigger pickoff from vertical amplifier unit (which allows simultaneous signal viewing and counting, and a trigger indicator analog CRT display to view the "shaped" input signal.

The following electrical characteristics are valid for instruments calibrated at an ambient temperature between $+20^{\circ} \mathrm{C}$ and $+30^{\circ} \mathrm{C}$ after a 20 minute warmup period.

# SECTION 2 OPERATING INSTRUCTIONS 

Change information, if any, affecting this section will be found at the rear of this manual.

## General

The 7D14 Digital Counter plug-in unit operates with the readout system of Tektronix 7000 -series Oscilloscopes to measure frequency or frequency ratio, and to totalize (count number of events). To effectively use the 7D14, the operation and capabilities of the instrument should be known. This section describes the function and operation of the controls and connectors, and gives first-time and general operating information.

## Installation

The 7D14 is designed to operate in any plug-in compartment of Tektronix 7000 -series oscilloscopes. However, certain modes of operation require the 7D14 to be installed in a specific compartment. The unit must be operated in a Horizontal compartment to count a signal which is being displayed on the CRT (see Counting a Displayed Signal). Operation in a Vertical compartment is necessary to view the 7D14 Trigger Indicator Display on the CRT (see Trigger Indicator Display).

To install the 7D14 into a plug-in compartment, push the unit in until it is seated flush against the front panel of the oscilloscope. To remove, pull the release latch to disengage the 7D14. Continue to pull the release latch to remove the unit from the oscilloscope.

## Display

The digital readout display for the 7D14 is presented on the CRT of the oscilloscope in which the unit is operated, along with information encoded by the other plug-in units. This display is written by the CRT beam on a time-shared basis with the analog waveform displays.

The digital display for the 7D14 will appear on the CRT in a location corresponding to the plug-in compartment used. The measurement data portion of the display will be in the top division of the CRT graticule area and the measurement units ( MHz or kHz ), when displayed, will appear in the bottom division.

It is not necessary to select the 7D14 with the oscilloscope Vertical or Horizontal Mode switches to view the
digital display. However, in order to view the 7D14 Trigger Indicator Display, selection with the Vertical Mode switch is required.

The readout display of the measurement data consists of four to eight digits depending on the measurement being made. All zeros to the left of the most significant digit are blanked out.

The measurement units and decimal position in the display are determined by the MEASUREMENT INTERVAL pushbutton selected. When the measurement range in use is exceeded, the display is preceded by a "greater than" symbol ( $>$ ).

## CONTROLS AND CONNECTORS

The major controls and connectors for operation of the 7D14 are located on the front panel of the instrument. These are shown in Fig. 2-1. Two auxiliary functions are provided by controls located inside the instrument. A description of the function and/or operation of the controls and connectors follows.

## Measurement Interval Controls

MEASUREMENT INTERVAL
$1 \mathrm{~ms}-10 \mathrm{~s}$ (one Selects one of five measurement millisecond through intervals from the internal time10 seconds)

MANUAL GATE
Seven self-cancelling pushbutton switches that select internal, external, or manual gate. base gates. A time-marker output with a period equal to the selected interval is provided at the MONITOR connector.

ON: Initiates gate interval (start count), and holds the gate open for totalizing.
OFF: Terminates gate interval (stop count), and starts display time. Also selects external gating signal from the EXT GATE connector.

GATE Indicator Lights during the active gating interval.

Fig. 2-1. 7014 front-panel controls and connectors.

EXT GATE/MONI-
TOR Connector

BSM connector for external gate input or time marker output as selected by MEASUREMENT INTERVAL pushbuttons.

## PRESET

## Display Time Controls

DISPLAY TIME Variable control to set the length of time the reading will be displayed after the count is made and before the next measurement is taken. Display time can be varied from 0.1 second to five seconds. $\infty$ (infinite) position (fully clockwise) provides continuous display until reset by an external signal or by pressing the RESET pushbutton.

RESET Pushbutton: Manually resets the counter to zero.
Pin-jack connector: Provides input for external signal to reset the counter to zero. VOLTS
$50 \Omega$
$1 \mathrm{M} \Omega$

## Reference Frequency/Channel B Controls

REF FREQ/CH B Pushbuttons that select the function of the EXT IN/MONITOR connector.

INT 1 MHz
(Internal 1 megahertz)

EXT IN
(external input)

Selects 1 MHz signal from internal crystal oscillator at MONITOR connector.

Selects external input to Channel B for an external timing standard, or for signal input for ratio measurements.

## Trigger Controls

LEVEL/SLOPE

Selects the amplitude point and slope on trigger signal where counter is triggered (VAR pushbutton pressed). When the indicator line on the outer ring is to the left of center, the counter is triggered on the positive-going slope of the input signal as shown by the positive-going edge symbol. To the right of center, the counter is triggered on the negative-going slope of the input signal as shown by the negative-going edge symbol.

INPUT SENS/P-P

BW (bandwidth) Pushbutton switches that select the

COUPLING

TRIG SOURCE Input signal provided from the indicator oscilloscope trigger pickoff circuitry. (This mode of operation enables simultaneous counting and CRT display of a signal. For more information, see Counting a Displayed Signal.) bandwidth of the trigger input circuits (affects signals from internal TRIG SOURCE and CH A INPUT connector).

525 MHz : Selects full bandwidth capability.
5 MHz : Limits upper bandwidth to about 5 megahertz $(-3 \mathrm{~dB}$ point).
Pushbutton that selects a fixed trigger point at the zero-volt level on the positive-going slope (LEVEL/ SLOPE control inoperative).

Pushbutton to allow manual selection of trigger level and slope with the LEVEL/SLOPE control.

Rotary switch that selects internal or external signal input to trigger counter and selects sensitivity.

Input signal provided from CH A INPUT connector at 50 -ohm input impedance.
1 V: Minimum signal amplitude must be one volt or greater.
100 mV : Minimum signal amplitude must be 100 mV or greater.

Input signal provided from CH A INPUT connector at one-megohm input impedance.
100 mV : Minimum signal amplitude must be 100 mV or greater.
1 V : Minimum signal amplitude must be one volt or greater.
10 V : Minimum signal amplitude must be 10 volts or greater.

Pushbutton switches that select the method of coupling the signal from the CH A INPUT connector to the trigger circuits (does not affect signals from internal TRIG SOURCE).

Fig. 2-2. Manual Gate Storage switch and Display Pos adjustment.

AC: Selects capacitive coupling to block DC signal components. This switch position is used for most signal measurements.
DC: Selects direct coupling to pass all components of the signal from $D C$ to the upper limit of the unit. This switch position is used mainly for DC and low. frequency signals.

CH A INPUT
(BNC connector)

Input connector for external signals.

## Internal Controls

See Fig. 2-2

Man Gate Storage
Slide switch

Selects manual gate storage mode (use with MANUAL or EXT GATE).

OFF (forward): Readout display follows the counter.

ON \{rear\}: Readout display is updated at the end of each gate interval.

Display Pos

Variable control to set the Trigger Indicator Display vertical position.

## FIRST-TIME OPERATION

## General

When shipped from the factory, the 7014 has been calibrated to meet the specifications listed in Section 1 and is ready to be used with a readout-equipped Tektronix 7000 -series Oscilloscope.

The following First-Time Operation procedure demonstrates the basic operation of the 7D14 controls. It is recommended that this procedure be followed completely for familiarization with the instrument.

## NOTE

The First-Time Operation procedure along with Table 2-1 can be used to provide a confidence check of the instrument's operation. These steps should be performed each time the 7D14 is placed in a different oscilloscope, and before each use.

## Preliminary Instructions

1. Install the 7D14 in any available plug-in compartment of a 7000 -series oscilloscope (referred to in this procedure as the Indicator Oscilloscope).
2. Connect the oscilloscope to a power source which meets the frequency and voltage requirements of the Indicator Oscilloscope power supply.
3. Turn the oscilloscope power on and allow about twenty minutes warmup time.
4. During the warmup period, set the controls as follows:

## indICATOR OSCILLOSCOPE

| Intensity | Counterclockwise |
| :--- | :--- |
| Readout | Off |

Any controls not mentioned can be set as desired.

| 7 l 14 |  |
| :--- | :--- |
| MEASUREMENT |  |
| INTERVAL | 10 s |
| DISPLAY TIME | Midrange |
| REF FREO/CH B | INT 1 MHz |
| TRIGGER | PRESET |
| INPUT SENS/P-P VOLTS | $1 \mathrm{M} \Omega / 1 \mathrm{~V}$ |
| BW | 5 MHz |
| COUPLING | AC |

## Digital Display Check

5. Advance the Readout control until a readout display is observed. Adjust the oscilloscope Focus and Astigmatism controls for a well-defined display.
6. Connect the 1 MHz signal from the EXT IN/ MONITOR connector to the CH A INPUT connector with a BSM male to BNC female adapter and a 50 ohm BNC cable.
7. The readout display should read $1000.0000 \mathrm{kHz} \pm 1$ count ( 999.9999 to 1000.0001 kHz ).
8. Check that the GATE indicator light is on during the time the 7D14 is counting ( 10 seconds).
9. Sequentially press the MEASUREMENT INTERVAL 1 s through 1 ms pushbuttons and check that the display corresponds to the readings given in Table 2-1.

TABLE 2-1
OPERATING CHECK DISPLAY

| MEASUREMENT <br> INTERVAL | READOUT LIMITS |  |  |
| :---: | :---: | :---: | :---: |
|  | MINIMUM | MAXIMUM |  |
| 10 s | 999.9999 | 1000.0001 | kHz |
| 1 s | 999.999 | 1000.001 | kHz |
| 100 ms | 0.99999 | 1.00001 | MHz |
| 10 ms | 0.9999 | 1.0001 | MHz |
| 1 ms | 0.999 | 1.001 | MHz |

10. Disconnect the cable and the adapter.

## GENERAL OPERATING INFORMATION

## Signal Connection

In general, probes offer the most convenient means of connecting signals to the 7D14 CH A INPUT. Tektronix probes are shielded to prevent pickup of electrostatic interference. A 10 X attenuation probe offers a high input impedance and allows the circuit under test to perform very close to normal operating conditions. Also, a 10X probe attenuates the input signal ten times.

Tektronix probes are designed to monitor the signal source with minimum circuit loading. The use of a probe will, however, limit the maximum bandwidth capability of the 7D14. To obtain maximum bandwidth when using probes, use a probe capable of compensating 20 pF ; use one of the $1 \mathrm{M} \Omega$ input impedance positions of the INPUT SENS/P-P VOLTS switch; and observe the grounding considerations given in the probe manuals. The probe-toconnector adapters and the bayonet-ground tip provide the best frequency response.

In high-frequency applications requiring maximum overall bandwidth, use a coaxial cable for the signal connection and a $50 \Omega$ input impedance position of the INPUT SENS/P-P VOLTS switch. To maintain the high-frequency characteristics of the applied signal, use high-quality, lowloss cable. Resistive attenuators can be used to minimize reflections if the applied signal has suitable amplitude.

A signal can also be routed to the 7D14 through an amplifier unit in a vertical plug-in compartment via the internal trigger pickoff circuitry of the Indicator Oscilloscope. This method of signal connection minimizes circuit loading for measurements requiring simultaneous counting and CRT display (see Counting a Displayed Signal).

## General Control Settings

Introduction. The following discussion provides control setup information for general measurement applications. Further information can be found under Controls and Connectors or in the discussion for a specific measurement mode (e.g., Frequency Measurements).

Trigger Controls. Signals to be counted may have a wide variety of shapes and amplitudes, many of which are unsuitable to drive the counting circuits. For this reason, the signals are first applied to signal conditioning circuits; then to the trigger circuit, where they are converted to rectangular pulses of uniform amplitude.

Signals often have characteristics which would prevent triggering or result in an erratic count. These signals must be conditioned before they are applied to the trigger input. The INPUT SENS, COUPLING, and BW switches provide means of conditioning the trigger signal. Obtaining a steady, reliable reading is dependent upon the proper setting of these controls and proper adjustment of the LEVEL/ SLOPE control.

The INPUT SENS/P-P VOLTS switch selects either internal routing of the signal from the Indicator Oscilloscope trigger circuitry or connection through the CH A INPUT connector. Operation in the TRIG SOURCE position requires that the 7D14 be installed in a horizontal plug-in compartment. The oscilloscope Trigger Source switch for that horizontal channel then provides further selection of the signal source. (For more information on this mode of operation, see Counting a Displayed Signal.)

For signals connected to the CH A INPUT connector, set the INPUT SENS/P-P VOLTS switch to select the desired input impedance. An input impedance of $50 \Omega$ should be used when coupling into a 50 -ohm system for highfrequency measurements. The $1 \mathrm{M} \Omega$ settings provide a higher input impedance for minimizing loading on the signal source.

Select a P-P VOLTS setting appropriate to the amplitude of the signal being measured. The P-P VOLTS figure on the front panel indicates the minimum signal amplitude which will produce a count. The best P-P VOLTS setting is one that is much larger than the largest noise signal anticipated,

## Operating Instructions-7D14

but where the signal is sufficiently larger than the P.P VOLTS setting to ensure a steady count. Generally, begin with the largest P-P VOLTS setting. Then decrease the switch setting if necessary to obtain a steady count.

The COUPLING switch determines the coupling between the CH A INPUT connector and the trigger circuit. Generally, use AC coupling to block the DC component of a signal. Otherwise, the DC component might cause the signal level to be bevond the range of the LEVEL/SLOPE control. DC coupling can be used for low-frequency signals, or for pulses with known DC levels. See Table 1-1 in the Specification section for the frequency range and amplitude limits for each coupling method. The COUPLING switch does not affect signals selected via the TRIG SOURCE position of the INPUT SENS switch.

The BW switch provides a means of filtering out highfrequency noise pulses which may cause erratic readings. Generaliy, use the 5 MHz setting unless the signal to be counted is above this frequency. The BW switch affects signals connected through both the internal TRIG SOURCE and the CH A INPUT connector.

The trigger circuit has a hysteresis (basic sensitivity) of approximately 100 millivolts. A typical signal waveform at the input to the trigger is shown in Fig. 2-3A. The hysteresis of the trigger is represented by the shaded area. Each time the signal level (including DC level) rises above the upper hysteresis limit $\varepsilon_{2}$, and falls below the lower hysteresis limit $e_{i}$, the trigger circuit produces a rectangular waveform as shown in Fig. 2-38. This rectangular waveform is the signal actually counted by the counting circuits.

Generally, the best point on a waveform for triggering the counter is where the slope is steep, and therefore usually free of noise Assuming a sine-wave signal waveform, the steepest slope occurs at the zero-crossing point.

Fig. 2-3. (A) Signal input to trigger; shaded area represents trigger hysteresis with PRESET button depressed. (B) Trigger output.

This is the point on the positive-going slope selected for triggering when the PRESET pushbutton is pressed, and is the condition represented in Fig. 2-3A and B.

Noise pulses or other signal components may be presented which are of sufficient amplitude to produce unwanted trigger pulses. A typical condition is represented in Fig. 2-4A. The resulting trigger pulses shown in Fig. 2-4B will cause an erratic or incorrect count.

Pressing the VAR pushbutton enables the LEVEL/ SLOPE control to be used to move the hysteresis above or below the 0 -volt level. The condition represented in Fig. 2-4A and $B$ can be corrected by using the LEVEL/SLOPE control to move the hysteresis to a level above or below the

Fig. 2-4. (A) Input signal with noise in PRESET hysteresis level; and (B) resultant trigger output.

Fig. 2-5. (A) Signal imput to trigger; Shaded area represents hysteresis set abowe noise pulses. (B) Resultant Trigger output.

Fig. 2-6. (A) Signal input to trigger; shaded area represents hysteresis set above noise pulses; (B) Trigger output with LEVEL/SLOPE con trol set in negative-slope region.
noise. Fig. 2-5A shows the signal with the hysteresis moved above the noise with the corrected trigger output shown in B. Fig. 2-6A and $B$ shows the same waveforms as in Fig. $2-5$, only with the LEVEL/SLOPE control set in the negative slope region. Note that the trigger pulse shown in Fig. 2-6B goes positive when the signal input goes negative.

Measurement Interval Controls. The MEASUREMENT INTERVAL switch selects the time interval (also called gate time) during which the 7D14 counts. The source of the pulses which control the time interval determines the measurement mode.

The internal gate circuits derive gate times from a one megahertz reference frequency signal to make frequency measurements. The gate times thus derived are selected by the $1 \mathrm{~ms}, 10 \mathrm{~ms}, 100 \mathrm{~ms}, 1 \mathrm{~s}$, and 10 s pushbuttons. The measurement interval selected determines the measurement range and resolution. These pushbuttons also automatically select the measurement units and decimal position in the display. Table 2-2 gives the frequency range and resolution for each time interval, and shows the display decimal position and measurement units.

Generally, use the shorter measurement intervals for high-frequency, low-resolution measurements and the longer intervals for measurements requiring high resolution.

Totalizing, or counting a number of events, is accomplished by counting during a time selected by the MANUAL GATE ON/OFF pushbuttons. The gate time is started by pressing the MANUAL GATE ON pushbutton, and stopped by pressing the OFF button. The manual mode is generally used to count a number of events for a relatively long, indefinite time. The 7D14 can be set to display
the total count at the end of the gate time or to display each count as it is made. Also, the 7D14 can add the counts made during successive gate times. (For further information, see Totalize under Measurement Modes.)

An external gating signal can be used to control the gate time or measurement interval. The gating signal is connected to the EXT GATE connector and is selected by pressing the MANUAL GATE OFF pushbutton. See the Specification section for external gate signal requirements.

REF FREQ/CH B controls. The INT 1 MHz pushbutton selects the internal crystal oscillator for use as a reference signal for frequency measurements. The one megahertz signal is available at the front-panel EXT IN/MONITOR connector when the INT 1 MHz button is pressed in.

When greater accuracy is required than is provided by the internal crystal oscillator, a one megahertz external timing standard can be connected to the EXT IN/ MONITOR connector. Pressing the EXT IN pushbutton selects the signal connected to the EXT IN connector.

The EXT IN connector and pushbutton are also used for making ratio measurements. The 7D14 will compare the frequency of the signal connected to the EXT IN connector to the frequency of the Channel $A$ signal. (For further information, see Ratio Measurements under Measurement Modes.)

Display Time Controls. The DISPLAY TIME control is used to set the length of time a measurement is displayed before the next measurement is started. The display time can be varied from at least 0.1 second to five seconds or longer.

The $\infty$ (infinite) detent position of the DISPLAY TIME control sets the 7D14 to display the last measurement indefinitely, or until reset by the RESET pushbutton or an external signal.

The display time circuit is locked to the 1 ms through 10 s MEASUREMENT INTERVAL pushbuttons so that the total display time is the sum of the DISPLAY TIME control setting and the measurement interval selected.

When used with manual gate operation, the DISPLAY TIME control determines when to totalize the counts made during separate gate intervals (for further information, see Totalize under Measurement Modes).

## MEASUREMENT MODES

## Introduction

The 7D14 has three primary measurement modes: frequency, ratio, and totalize (number of events). The following discussion gives general information about each mode and instructions on making the measurements.

## Frequency Measurements

The 7D14 provides direct measurement of the average frequency of signals up to 525 MHz . The input to the counting circuits is selected by the INPUT SENS/P-P VOLTS control from either the signal connected to the CH A INPUT connector or the internal trigger pickoff signal from the Indicator Oscilloscope trigger circuits. (TRIG SOURCE; see Counting a Displayed Signal).

The 7D14 counts the input pulses over an interval selected by the MEASUREMENT INTERVAL 1 ms through 10 s pushbuttons. The measurement interval selected determines the measurement range and resolution. These pushbuttons also automatically select the measurement units and decimal point position in the display. Table 2-2 gives the frequency range and resolution for each time interval and shows the display decimal point position and measurement units.

Generally, use the shorter measurement intervals for high-frequency, low-resolution measurements and the longer intervals for measurements requiring high resolution.

Greater Accuracy. For greater accuracy and/or stability when measuring frequency, an external 1 MHz crystal signal can be substituted for the internal time-base oscillator. The external signal must have greater accuracy than the internal oscillator (see Specification section) and have a minimum amplitude of 0.8 volt peak-to-peak.

TABLE 2-2
MEASUREMENT INTERVAL DATA

| MEASUREMENT |  |  | MAXIMUM FREQUENCY |
| :---: | :---: | :---: | :---: |
| INTERVAL | UNITS | RESOLUTION |  |
| 1 ms | MHz | 1 kHz | 525.000 MHz |
| 10 ms | MHz | 100 Hz | 525.0000 MHz |
| 100 ms | MHz | 10 Hz | 525.00000 MHz |
| 1 s | kHz | 1 Hz | $99999.999 \mathrm{kHz}^{1}$ |
| 10 s | kHz | 0.1 Hz | $9999.9999 \mathrm{kHz}^{1}$ |

[^0]Connect the external signal to the REF FREQ/CH B EXT IN connector and press the EXT IN pushbutton. The function of the MEASUREMENT INTERVAL $1 \mathrm{~ms}-10 \mathrm{~s}$ pushbuttons is the same as when using the internal timebase oscillator.

## Ratio Measurements

Ratio measurements compare the frequencies of two signals. Normally, the higher frequency signal is applied to Channel A (via CH A INPUT connector or internal TRIG SOURCE) and the lower frequency signal is applied to Channel B (via EXT IN connector with the REF FREQ/CH B EXT IN pushbutton pressed). The MEASUREMENT INTERVAL 1 ms through 10 s pushbuttons select the counting time as derived from the signal applied to Channel B. The 7D14 then counts the pulses derived from the Channel A signal during a time interval established by the Channel $B$ signal.

The display ratio measurement is equal to:

$$
\frac{\text { Frequency Channel } \mathrm{A}}{\text { Frequency Channel B }} \times 10^{6} \times
$$

## MEASUREMENT INTERVAL

whose denominator is known to be 1 . Thus, a ratio of 30.000:1 will be displayed as 30.000 . The decimal point in a ratio measurement display is correctly positioned only when using the $1 \mathrm{~ms}, 10 \mathrm{~ms}$, or 100 ms MEASUREMENT INTERVAL pushbuttons. Readings obtained when the 1 s or 10 s buttons are pressed must be multiplied by $1 \sigma^{3}$ to correct the decimal position.

Ratio measurements are dimensionless (i.e., no measurement units); however, the MHz or kHz legend will remain displayed.

## Totalize (Count Number of Events)

Introduction. The 7D14 will count the number of pulses applied to Channel A (via the CH A INPUT connector or TRIG SOURCE) up to $99,999,999$ pulses at a rate not to exceed 525 megahertz. The pulses will be counted during a time interval (gate time) determined either by the MANUAL GATE ON/OFF pushbuttons or by a gating signal connected to the EXT GATE input connector. Overranging (count exceeding $99,999,999$ ) is indicated by a "greater than" symbol $(>)$ preceding the digital readout.

Display Storage Modes. Two modes of displaying the count can be selected when using MANUAL or EXT GATE operation. These modes are selected by the Man Gate Storage switch.

With the Man Gate Storage switch ON, the total count is displayed at the end of the gate or count interval.

This is the mode normally used for EXT GATE applications when counting a number of events within short, repetitious gate times. The advantage of using the storage ON mode is that no display flicker is observed during the count cycle. The last measurement taken remains displayed until the next measurement has been completed and is ready to be displayed. This is the same mode used when making frequency measurements with the gate time determined by the 1 ms through 10 s pushbuttons.

In the storage OFF mode, each count is displayed as it occurs; thus, the display always indicates the total count at that time. This mode is normally used with MANUAL GATE operation when counting a number of events over a relatively long, indefinite time. A typical application would be counting items passing a transducer on an assembly line.

Display Time. In the usual application (MANUAL GATE operation only), in which pulses are counted over one interval only, the DISPLAY TIME control functions in its usual manner; i.e., the display will be reset to zero after the display time has elapsed. However, if it is desired to add one interval to the next (totalize the count), the DISPLAY TIME control should be set to $\infty$. The same effect will be obtained whenever another gate interval is initiated before the display time has elapsed.

In EXT GATE applications, where the gate times are repetitious, the external gating signal is locked to the display timer circuitry. Thus, after one measurement has been taken, another gate interval will not be initiated until the completion of either the display time or the gate "off" time, whichever is longer. In this way, one interval is not added to another.

Using the MANUAL GATE. To make a count measurement using the MANUAL GATE ON/OFF pushbuttons, proceed as follows:

1. Set the internal MAN GATE STORAGE switch for the desired mode. (The OFF position is usually used for long gate intervals.)
2. Install the 7D14 in any available plug-in compartment of the Tektronix 7000 -series oscilloscope.
3. Turn the oscilloscope power on. Allow about 20 minutes warmup.
4. Advance the oscilloscope Readout control to obtain a usable readout display.
5. Connect the input signal to the CH A INPUT connector.
6. Set the INPUT SENS/P-P VOLTS, COUPLING, BW, and TRIGGER LEVEL/SLOPE controls as necessary to obtain a steady count.
7. Set the DISPLAY TIME control to $\infty$ (fully clockwise).
8. Depress the MANUAL GATE ON pushbutton and the counter will start counting. If necessary, press the RESET pushbutton so that the count will start from zero.
9. To terminate the count, depress the OFF button.

Using the External Gate. To make a count measurement using an external gating signal, proceed as follows:

1. Set the internal Man Gate Storage switch for the desired mode. (The ON position is usually used for short gate intervals.)
2. Install the 7D14 in any available plug-in compartment of a Tektronix 7000 -series oscilloscope.
3. Turn the oscilloscope power on. Allow about 20 minutes warmup.
4. Advance the oscilloscope Readout control to obtain a usable readout display.
5. Connect the input signal to the CH A INPUT connector.
6. Connect the external gating signal to the EXT GATE input connector through the BSM to BNC male adapter (supplied accessory). The external gating signal must meet the input requirements as given in Section 1 of this manual.
7. Set the 7D14 TRIGGER controls as necessary to obtain a steady count.

The external gate function can be used in conjunction with a delayed sweep to count the quantity of pulses within a burst. The 7D14 external gate input is driven by the delayed-sweep gate output to count the number of pulses within the delayed-sweep time (intensified zone). To use this function, proceed as follows:

1. Set the internal Man Gate Storage switch for the desired mode. (The ON position is usually used for short gate intervals.)

Fig. 2-7. Counting the number of pulses within a burst.
2. Install the 7D14 in a vertical plug-in compartment.
3. Connect the input signal to the CH A INPUT and amplifier unit input connectors via a BNC T connector and short BNC cable.
4. Connect the delayed gate output to the EXT GATE connector through a BSM to BNC male adapter (supplied accessory).
5. Press the MANUAL GATE OFF pushbutton.
6. Turn the oscilloscope power on. Allow about 20 minutes warmup.
7. Advance the oscilloscope Readout and Intensity controls as necessary to obtain a usable display.
8. Set the delaying time-base unit Time/Div control to view several cycles of the input-signal waveform as shown in Fig. 2-7.
9. Set the delaying time-base unit Delay Time Mult and the delayed time-base Variable Time/Div controls to intensify the pulses to be counted (see Fig. 2-7).
10. Set the 7D14 TRIGGER controls as necessary to obtain a steady count.

## OPERATING MODES

## Counting a Displayed Signal

This mode of operation enables simultaneous counting and CRT display of a signal. The CRT display is obtained in the usual manner; i.e., the signal is connected to an amplifier unit in a vertical plug-in compartment and a time-base unit in a horizontal compartment provides the sweep. The
signal is routed to the 7D14 from the amplifier unit trigger pickoff through the oscilloscope trigger source selection circuitry. This necessitates operating the 7D14 in one of the horizontal compartments of an oscilloscope which can accommodate four plug-in units.

The INPUT SENS/P-P VOLTS switch selects the signal from the amplifier unit when it is set to TRIG SOURCE. The Trigger Source switch for the horizontal compartment containing the 7D14 must be set to select the vertical compartment originating the signal to be counted. In addition, dual-trace amplifier units contain further trigger source selection. This must be set to select the correct channel.

Signals selected in the TRIG SOURCE position are AC coupled which limits the low-frequency response. The highfrequency response is limited by the bandwidth of the amplifier unit being used.

This mode of operation is more convenient for simultaneous measurements than using separate probes for counter and oscilloscope. Also, one signal connection places less load on the circuit under test than if separate probes were used. An added advantage is being able to use the amplifier unit to amplify signals whose amplitude would otherwise be insufficient to trigger the 7D14.

## Trigger Indicator

The output of the 7D14 trigger circuit can be displayed on the CRT, along with the signal being counted. The 7D14 controls can then be adjusted while observing the CRT display for triggering at the desired point on the waveform.

To use this mode of operation, the 7D14 must be operated in a vertical plug-in compartment. The signal to be measured is connected to the CH A INPUT connector and to the input of the other vertical unit using a $T$ connector. The two waveforms can then be displayed by setting the oscilloscope Vertical Mode to Alt or Chop.

The "Trigger Indicator" is a rectangular waveform display with a nominal amplitude of 0.2 division peak-to-peak. Proper triggering is indicated when the "Trigger Indicator" waveform matches the signal waveform frequency and duty cycle as shown in Fig. 2-8.

The Trigger Indicator display vertical position is set to the CRT center at the factory. However, the display can be positioned for the convenience of the operator with the internal Display Pos adjustment R866 (see Fig. 2-2). To make this adjustment, use the following procedure:

1. Remove the Indicator Oscilloscope left cover and the 7D14 left side shield.

Fig. 2-8. Upper trace: Trigger Indicator waveform; lower trace: input signal waveform.
2. Install the 7014 in the Indicator Oscilloscope left vertical plug-in compartment.
3. Connect the input signal to the 7 D 14 CH A INPUT and amplifier unit Input connectors using a BNC T connector and short BNC cable.
4. Set the Indicator Oscilloscope Vertical Mode switch to Chop,
5. Adjust the Display Pos adjustment R866 to position the Trigger Indicator display as desired.

At higher frequencies, care should be taken that the delays to the vertical plates of the CRT match reasonably well. If these delays are not the same, the presentation will not be a correct indication of the triggering point. A delay cable between the CH A INPUT connector and the T connector can be used to adjust the delay difference between the 7D14 and the amplifier unit.

# SECTION 3 CIRCUIT DESCRIPTION 

Change information, if any, affecting this section will be found at the rear of this manual.

## Introduction

This section of the manual contains a description of the circuitry used in the 7D14 Digital Counter Plug-In. The description starts with a block diagram. Following the block diagram description is a discussion of the control signals generated within the instrument. After the control signals discussion is a more detailed circuit description, particularly for circuits unique to this instrument. If more information is desired on commonly used circuits, refer to the following textbooks:

Jacob Millman and Herbert Taub, "Pulse, Digital, and Switching Waveforms", McGraw-Hill, New York, 1965.

Tektronix Circuit Concepts Book (order from your local Tektronix Field Office or representative):

Digital Concepts, Tektronix Part No. 062-1030-00.

Following the detailed circuit description is a brief discussion of the readout system used in Tektronix 7000 -series Oscilloscopes. If more information is desired on the readout system, refer to the instruction manual for the oscilloscope.

## Logic Fundamentals

Signal lines in this instrument are named to indicate the state at which their particular function is performed. For example, the line labeled "RESET" means that the affected circuit(s) is reset when this line is HI ; the line labeled " $\overline{\mathrm{DCU}}$ RESET". (DCU RESET - NOT) means that the affected circuits are reset when this line is LO.

Digital logic techniques are used to perform many functions within this instrument. The function and operation of the logic circuits are described using logic symbology and terminology. For further information, see Logic Fundamentals in Section 3 of the oscilloscope instruction manual.

## NOTE

All references to direction of current in this manual are in terms of conventional current; i.e., from plus to minus.

## BLOCK DIAGRAM

The following discussion is provided to aid in understanding the overall concept of the 7D14 before the individual circuits are discussed in detail. A basic block diagram of the 7D14 is shown in Fig. 3-1. A more detailed block diagram is given in the Diagrams section. Only the basic interconnections between the individual blocks are shown on the block diagram. Each block represents a major circuit within the instrument. The number on each block refers to the schematic on which the complete circuit is found.

Signals to be counted are applied to the Channel A Signal Conditioning circuit via either the CH A INPUT connector or the oscilloscope trigger pickoff circuitry. The Channel A Signal Conditioning circuit selects and conditions the input signal to generate a uniform trigger output (Clock). The Clock output is switched on and off by the GATE signal from the Time Base and Control circuit to drive the First Decade Counter. Also, an output from the Trigger Generator (prior to the gated stage) is provided to the oscilloscope vertical system to be displayed on the CRT.

The First Decade Counter circuit is the $10^{0}$ decade or units counter of the 7D14. This circuit counts the Channel A Signal Conditioning circuit Clock output, and provides a units-count, binary-coded-decimal (BCD) output to the Counter and Readout Encoding circuit. At the tenth Clock input, the First Decade Counter circuit provides a CARRY output to the Counter and Readout Encoding circuit.

The Counter circuit counts the $\overline{\text { CARRY }}$ output from the First Decade Counter, and translates the count to a BCD form. This BCD data, along with the BCD output from the First Decade Counter, is stored in the Storage Registers. Upon command of the Time Base and Control circuit $\overline{\text { DIS- }}$ $\overline{\mathrm{P} L A Y}$ output, the stored BCD data is transferred to the Readout Encoding circuit.

The Readout Encoding circuit sequences the BCD data to encode data so the oscilloscope readout system can display a digital readout of the count. The sequencing is determined by the time-slot inputs from the oscilloscope readout system to ensure proper placement of each digit in the

Fig. 3-1. 7D 14 basic block diagram.
readout display. This circuit also encodes the readout system to display appropriate measurement units, decimal position, and over-range indication.

The Time Base and Control circuit provides logic level outputs to the other 7D14 circuits to determine when the counter is allowed to count, when the readout display is updated, and when the counter is reset. These output signals are described under Control Signals in this section.

## Control Signals

The 7D14 counts pulses and encodes the oscilloscope readout system to display the resultant count. The total count is equal to the pulse rate multiplied by the time the counter is allowed to count.

The signals which determine when the counter is allowed to count, when the readout display is updated, and when the counter is reset are generated in the Time Base and Control circuit. The generation and the time-relationship between these signals are determined by the settings of the MEASUREMENT INTERVAL, DISPLAY TIME, REF FREQ/CH B, and Manual Gate Storage controls. These control settings, in conjunction with external signals (when used), determine the 7D14 measurement mode. The function of the 7D14 controls and connectors is described in Section 2. A complete description of the Time Base and Control circuit is given later in this section. The following brief description of these control signals is provided to aid
in understanding the signals as they are used in the other circuits.

The Time Base and Control circuit outputs are the GATE, DISPLAY, and DCU RESET. These output logic levels are represented in Fig. 3-2. Fig. 3-2 also shows the time-relationship that exists between the outputs in the usual operating modes.

GATE.The GATE output indicates when the counter is allowed to count. When this output level is $\mathrm{HI}\left(\mathrm{T}_{1}\right.$ to $\left.\mathrm{T}_{2}\right)$, the GATE is "on"; and the counter counts the input signal. The front-panel GATE indicator lamp is on during the GATE "on" time. The GATE "on" time is determined by the MEASUREMENT INTERVAL switch setting (see Section 2).
$\overline{\text { DISPLAY }}$.This output indicates when the readout display is to be updated. When this output level is LO, the measurement made by the counter is transferred to the readout display. For most operating modes, DISPLAY is generated at the end of the GATE "on" time ( $\mathrm{T}_{2}$ ).

DCU RESET.This output indicates when the counter is to be reset to zero. When this output level is LO, the counter is reset to zero. $\overline{\text { DCU RESET }}$ is generated at $T_{4}$, at a time after $\mathrm{T}_{2}$ as determined by the DISPLAY TIME control.

Fig. 3-2. Time Base and Control circuit control signal outputs.

## DETAILED CIRCUIT DESCRIPTION CHANNEL A SIGNAL CONDITIONING

## General

A detailed block diagram of the Channel A Signal Conditioning circuit is shown in Fig. 3-3. The phase relationship between the input signal and the Clock output can be selected by the SLOPE control to be in phase or out of phase with one another. When the SLOPE control is set in the positive-slope region, the input signal is in phase with the Clock output signal. A schematic of this circuit is shown on Diagram 1 in the Diagrams section.

Direct coupling is used between stages throughout the Channel A Signal Conditioning circuit (except the Trigger Source Amplifier). Feedback from the output of the Trigger Generator to the minus ( - ) input of the Input Amplifier through the Feedback Amplifier stabilizes the DC levels of the stages within the feedback loop. Thus, drift due to temperature offsets and/or bandwidth switching is minimized. An internal Zero adjustment sets the voltage level at the plus input of the Input Amplifier to adjust the quiescent DC levels of all stages within the feedback loop. The triggering LEVEL control sets the current into the summing point at the minus input of the Input Amplifier to provide a front-panel adjustment of the Trigger Amplifier output DC level.

## COUPLING Switch

Signals applied to the CH A INPUT connector can be AC-coupled or DC-coupled to the Input Amplifier. The input coupling relay, K100, is actuated by COUPLING switch S5. When the AC button is pressed, K100 is actuated to pass the signal through C1 to the Input Sensitivity relays. When the DC button is pressed, K100 is not actuated. The
signal is connected directly from the CH A INPUT connector to the Input Sensitivity relays.

## INPUT SENS Switch

Signals to be counted are applied to the minus input of the Input Amplifier through the CH A INPUT connector, Input Coupling Relay, and the Input Sensitivity relays; or, to the plus input through the Interface Connector (oscilloscope trigger pickoff signal) and the Trigger Source Amplifier stage. INPUT SENS switch S10 selects the signal input and sets the attenuation ratio/input impedance for signals connected to the CH A INPUT connector.

Switching of the CH A INPUT signal is accomplished by means of relays, K101-K103-K106, actuated by S10. When S10 is set to TRIG SOURCE,+15 volts is applied to the Trigger Source Amplifier to turn it on. At the same time, the switching relays disconnect the CH A INPUT signal from the Input Amplifier.

When S 10 is set to the 100 mV sensitivity setting ( $50 \Omega$ or $1 \mathrm{M} \Omega$ ), relays K 101 and K 103 connect the CH A INPUT signal from the Input Coupling Relay to the Input Amplifier. Resistor R112 establishes a one-megohm input impedance in the $1 \mathrm{M} \Omega$ position of the INPUT SENS switch. A network consisting of R107-R108-LR108-R109-R110 is switched in by relay K 106 in the $50 \Omega$ positions to provide a 50 -ohm input impedance.

R101-R102-R103-R104-R105 form a 10X-100X attenuator network. C101-C102-C103-C105 compensate this attenuator network for high-frequency signals. For S10

settings of 1 V , the signal is applied to the junction of R103 and R104 through relay K103S1; the output is taken from the junction of R104-R 105 through relay K103S2. For the S10 setting of 10 V ( $1 \mathrm{M} \Omega$ only), the signal is applied to the junction of R101-R102 through relay K101S1; the output is taken from the junction of R104-R 105 through relay K103S2. R101 re-establishes the $1 \mathrm{M} \Omega$ input impedance when S 10 is set to the 10 V position.

## Trigger Source Amplifier

The Trigger Source Amplifier amplifies oscilloscope trigger pickoff signals from the Interface Connector in the TRIG SOURCE position of the INPUT SENS switch, and applies the signal to the Input Amplifier through C222-C223. Since the output of the Trigger Source Amplifier is applied to the plus input of the Input Amplifier, the trigger pickoff - Trig In signal is amplified by this stage. This maintains the same phase relationship to the Clock output as a signal applied to the CH A INPUT connector.

Resistor R212 establishes the input resistance for this stage. Also, R212, in conjunction with R871, provides a load for the oscilloscope trigger pickoff circuitry. The input signal is coupled through C212-R214 to the base of 0216. C212 blocks the DC component of the trigger pickoff signal; otherwise, the DC level of the signal will be affected by the vertical unit position control(s).

## Input Amplifier

The Input Amplifier stage consists of Q130A-B, Q132, and Q232. This stage is a wide-bandwidth operational amplifier that converts the single-ended input signal to a differential (push-pull) signal to drive the Bandwidth Selection stage. The minus input of the operational amplifier is the gate of Q130A, and the plus input is the gate of Q130B.

The minus input is the summing point for input signals (from the CH A INPUT connector), the triggering LEVEL (or Preset) control current, and negative-feedback signals. CR114-CR115-CR116-CR117 form a diode clamp network to protect the input components from damage due to excessive input voltages. These diodes will conduct only if the voltage at the summing point exceeds about $\pm 1.2$ volts.

Negative feedback from the output of the Input Amplifier through C132-R113, and through L134-C119-R119-R117-R113 to the minus input compensates the high-frequency response of this stage. C132 provides high-frequency compensation.

The sum of the currents into the minus input summing point sets the Trigger Amplifier output DC level as determined by PRESET-VAR switch S20. When the PRESET
button is in, the voltage level at the junction of R121-R126-R127-R128 is determined by R125, Preset. R125 adjusts the current into the summing point through R128-R117-R113 to balance the Trigger Amplifier outputs for a zero-volt difference. When the VAR button is in, the voltage set by R22 (LEVEL) is connected to the junction of R121-R126-R127-R128 through R121 to provide frontpanel adjustment of the triggering point.

## Bandwidth Selection

The Bandwidth Selection stage consists of fivemegahertz (MHz) amplifier Q136-Q236, 525-MHz amplifier Q141-Q241, and associated components. The BW switch, S8, selects the bandwidth by providing an emitter ground return for one of the two bandpass amplifiers. Diode clamps, CR135-CR136 and CR235-CR236, protect the transistors from damage due to excessive input voltage.

The bandwidth of transistor-pair Q136-Q236 is limited to about five MHz by inductors L134-L135-L138 and L234-L235-L238. When the BW switch 5 MHz button is in, emitter resistors R135 and R235 are returned to ground through R138 to enable Q136-Q236. When the 525 MHz button is in, the ground return for $\mathrm{Q} 136-\mathrm{O} 236$ is disconnected; +15 volts through R137 to R135-R235 ensures cutoff of Q136-0236.

The bandwidth of transistor-pair Q141-Q241 exceeds 525 MHz . When the 525 MHz button is in, emitter resistors R140-R240 are returned to ground through R238 to enable Q141-0241. When the 5 MHz button is in, this ground return is disconnected; +15 volts through R237 to R140-R240 ensures cutoff of Q141-Q241.

## Trigger Amplifier

The Trigger Amplifier stage consists of emitter coupled pair Q147-Q247, and associated components. This stage provides amplification for the differential signal from the Bandwidth Selection stage to drive the Trigger Generator.

## Trigger Generator

The Trigger Generator consists of Q152, Q252, Q154, Q254, and associated components. This stage shapes the output signal from the Trigger Amplifier to provide a trigger pulse with a fast leading edge to the Slope Switching stage.

Q152 and Q252 are emitter-coupled current switches. Emitter-followers Q154 and Q254 feed the output signals back to the opposite inputs. The differential signal at the collectors of Q154 and Q254 is applied to the Feedback Amplifier stage.

## Feedback Åmplifier

The Feedback Amplifier converts the Trigger Generator differential output to a single-ended signal to provide negative feedback to the Input Amplifier. This stage consists of an integrated-circuit (IC) operational amplifier U161. Feedback from the output of U 161 at pin 6 is connected to the minus input through R161.

## Slope Switching

The Slope Switching stage connects the Trigger Generator differential output to the Gate and Trigger Indicator Pickoff inputs. Slope switching is accomplished by means of relays K152-K252 (in conjunction with Q259), as determined by the PRESET-VAR and SLOPE switches.

When the PRESET button is in, positive ( + ) slope triggering is selected, regardless of the LEVEL SLOPE control setting. This sets the relays to connect the Trigger Generator + and - outputs to the Gate + and - inputs respectively (i.e., in phase).

When the VAR button is in, the trigger slope is determined by the SLOPE switch setting. In that SLOPE switch position, the circuit operation is the same as described for PRESET. When the SLOPE switch is set to,-+15 volts applied to K252 and to the base of Q259 reverses the state of the relays; this reverses the phase of the signal connection to the Gate.

## Trigger Indicator Pickoff

The Trigger Indicator Pickoff stage consists of Q855 and Q859. This stage provides an analog signal output to the oscilloscope through the Interface Connector to display the Trigger Generator output on the CRT. A Trig Out signal is also provided to trigger a time-base unit. R866, Display Positioning, adjusts the output voltage levels to set the vertical position of the CRT display.

## Gate

The Gate stage consists of input emitter-coupled pair Q170-0270, output emitter-coupled pair Q180-Q280, signal switches Q275-Q278, and tunnel-diode CR174. This stage connects the differential signal at its inputs to the Binary Driver stage on command of the complementary GATE and $\overline{\text { GATE }}$ inputs.

The + and - inputs to this stage are the bases of Q170 and 0270 respectively. Reference zener diode VR178 establishes a low-impedance, -7.5 -volt reference level at the base of Q180. Decoupling for the -7.5 -volt reference level is provided by C178. Reference zener diode VR176 estab-
lishes a low-impedance, -2.5 -volt reference level at the cathode of tunnel-diode CR174. Decoupling is provided by C176.

Signal switching is accomplished by connecting the signal at the collector of Q270 through either Q278 or Q275 as determined by the state of tunnel-diode CR174. Tunnel-diode CR 174 must be in its high state for $\mathbf{Q} 275$ to be forward biased, and in its low state for Q278 to be forward biased.

Tunnel-diode CR 174 is switched into its high state when GATE is HI with respect to GATE (GATE "on") and Q170 is forward biased. When tunnel-diode CR 174 is in its high state, Q275 is forward biased to connect the Q270-collector signal to the base of Q280. Q180-Q280 act as a paraphase amplifier to provide a differential-current output to the Binary Driver through T183.

When $\overline{\mathrm{GATE}}$ is HI with respect to GATE (GATE "off"), CR174 is switched back to its low state, regardless of the state of Q170. The low state of CR 174 forward biases Q278 and reverse biases Q275. This connects the Q270collector signal to the low-impedance, -7.5 -volt referencelevel point to turn off the Gate stage.

## Binary Driver

Q190-Q290 amplify the differential-current input from the Gate to the current level necessary to provide a Clock output to the Binary Counter (First Decade Counter circuit). Diode-connected $\mathbf{Q} 288$ provides a temperature-compensated voltage level at the bases of Q190-Q290 and Q188. Q188 acts as a constant-current source to supply the emitter current for Q190-Q290.

## FIRST DECADE COUNTER

## General

A detailed block diagram of the First Decade Counter circuit is shown in Fig. 3-4. An input/output table for the First Decade Counter circuit is shown in Fig. 3-5. A schematic of this circuit is shown on Diagram 2 in the Diagrams section.

The Binary Counter Voltage Regulator provides two temperature-compensated operating voltages to the Binary Counter integrated circuit. These output voltages are derived from the oscilloscope -15 -Volt power supply.

The Binary Counter stage counts the Clock input, and provides a binary-coded output. The Binary Counter output provides the $2^{0}$ bit of the BCD output to the $10^{0}$ Storage

Fig. 3-4. First Decade Counter circuit detailed block diagram.

Fig. 3-5. Input/output table for First Decade Counter circuit.

Register (Counter and Readout Encoding circuit) through Q339. Also, the Binary Counter output drives the Quinary Counter through the Quinary Driver stage.

The Quinary Driver shapes the Binary Counter output to provide a more constant-amplitude output to drive the Quinary Counter. The Quinary Counter (divide-by-five counter) counts the Binary Count, and provides a HI level on one of five output lines to the BCD Encoder. The HI
level output line indicates a Quinary Count of 0-1, 2-3, 4-5, 6-7, or 8-9. The BCD Encoder translates the Quinary Counter output to encode the $2^{1}, 2^{2}$, and $2^{3}$ bits of the BCD output.

The Carry Comparator detects the tenth Clock input to the First Decade Counter circuit to provide the CARRY output ( aHI to LO level transition; see Fig. 3-5).

The Reset Driver provides the HI level RESET and CLEAR outputs on command of the $\overline{\mathrm{DCU} \text { RESET }}$ input from the Time Base and Control circuit. These outputs reset the Binary and Quinary Counter stages to the zerocount state.

## Binary Counter Voltage Regulator

Negative 15 volts from the oscilloscope power supply is applied to series Regulator Q317 to provide a -8.5 -volt output. U305A and U305B (U305 is a five-transistor array IC) are connected as a comparator. Reference voltage for the comparator is provided by voltage divider R300-R301-R302, which sets the base of U305B at about -8.5 volts. The comparator output sets the base level of Series Regulator Q317 through emitter-followers U305DU305E.

A voltage divider consisting of R327 and U305C provides the Reference Voltage output from -8.5-volt supply. R320, Ref Voltage, adjusts the base level of U305C to set the Reference Voltage output to about -3.5 volts.

## Binary Counter

The Binary Counter consists of IC U329 and transistor Q339. The + and - Clock inputs toggle U329 to provide a Binary Count output with a repetition rate one-half that of the Clock input. The U329-0 output drives the Quinary Counter through the Quinary Driver stage. Q339 isolates the U329-1 output from the BCD-output $2^{0}$ bit.

The Reset Driver CLEAR output is applied to $U 329$ pin 1 through CR357. When the CLEAR level is HI, U329 is cleared for a LO 1 output.

## Reset Driver

The Reset Driver stage provides the RESET and CLEAR outputs to the Binary Counter and Quinary Counter stages respectively upon command of the Time Base and Control circuit $\overline{\mathrm{DCU}}$ RESET output.

The quiescently HI level $\overline{\mathrm{DCU}}$ RESET input is applied to the emitter of O535 through CR351-R351. When the $\overline{\mathrm{DCU}}$ RESET input goes LO, the HI to LO level transition momentarily forward biases Q353. This produces a negative-going pulse on the collector of Q353. The negativegoing pulse is applied directly to the base of Q356, and from the emitter of Q 356 to the base of Q359 through C358-R359. As this results in a forward-bias condition for Q356 and reverse bias for Q359, the collectors of both transistors momentarily go HI to provide RESET and CLEAR outputs.

## Quinary Driver

Q341-Q345 are connected as an emitter-coupled Schmitt multivibrator. The 0-output of Binary Counter U329 is connected to the base of Q341 through zener diode VR331 to trigger the multivibrator. The output is taken from the collector of Q345. When the Binary Counter- 0 output is HI , Q341 conducts and Q345 is turned off. Therefore, the Quinary Driver Binary Count output is in phase with the U329-0 output.

## Quinary Counter

The Quinary Counter is made up of five Schmitt multivibrators, connected together to form a ring counter. Each multivibrator (multi) receives the Binary Count input. However, the ring counter configuration is such that an input will change the state of only one multi. In turn, this condi-
tions the succeeding multi to respond to the next input, etc. A resistor network between the multi outputs compares the state of each multi to the state of both the preceding and succeeding multis to provide the output to the BCD Encoder.

A simplified diagram of the Quinary Counter is shown in Fig. 3-6(A). Each multi is made up of two transistors. The multis are identified in Fig. 3-6(A) as multi A, Q362-Q364; B, Q374-Q376; C, Q382-Q384; D, Q390-Q392; and E, Q400-0402. The output load resistor is shown above the left transistor of each multi. The left transistor in each multi receives the Binary Count input.

In each multi, the emitter-resistor current (e.g., $I_{a}$ ) will flow through the transistor which has the more positive base level. The current through a multi load resistor is determined by the state of the corresponding multi and the preceding one. Therefore, the load resistor current can be at one of three levels; and, this will result in one of three voltage levels dropped across the load resistor. For example, the voltage dropped across load resistor $B$ may be due to one current unit ( $I_{a}$ or $I_{b}$ ), two current units ( $I_{a}+I_{b}$ ), or zero. The voltage levels resulting from zero, one, and two current units through a load resistor are represented in Fig. $3-6(B)$; and, are labelled,+ 0 , and - respectively.

The RESET input resets the Quinary Counter to the zero-count state. The momentary HI RESET level is applied to the base of the left transistor in each multi through R361-R348, and to the right transistor in multis $A$ and $C$ through R365 and R385 respectively. This causes the left transistor in multis B, D, and E to have the more positive base and the right transistor in multis $A$ and $C$ to have the more positive base. As a result, emitter-resistor current flows through the right transistor in multis A-C, and through the left transistor in multis B-D-E.

The reset, or zero-count, state of each multi is shown in Fig. 3-6(A) by the direction of the arrow representing emitter-resistor current. The resultant voltage dropped across each load resistor is $A,+; B,-; C,+; D,-;$ and $E, 0$. The multi output voltage is applied to the base of the right transistor through a zener diode. The zener diode lowers the base voltage level; however, the relative voltage level between the right transistor bases remains the same.

Fig. 3-7(A) shows the Quinary Driver Binary Count output in relation to the Clock input to the Binary Counter. At the first Clock input, the Binary Count output goes LO. This pulls the base of each left transistor LO towards a reverse-bias condition. Since the left transistors in multis $A$ and $C$ are already non-conducting, the LO input has no effect. Due to the voltage across the load resistors (- level), the bases of the right transistors of multis $B$ and $D$ are

(A)

|  | CLOCK | OUTPUT LEVEL |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | COUNT | A | B | C | D | E |
| RESET | 0 or 10 | + | - | + | - | 0 |
|  | 1 | 0 | - | + | - | + |
|  | 2 | - | 0 | + | - | + |
|  | 3 | - | $+$ | 0 | - | + |
|  | 4 | - | + | - | 0 | + |
|  | 5 | - | + | - | + | 0 |
|  | 6 | 0 | + | - | + | - |
|  | 7 | + | 0 | - | + | - |
|  | 8 | $+$ | - | 0 | + | - |
|  | 9 | + | - | + | 0 | - |

(B)

Fig. 3-7. (A) Clock count input vs. Quinary Driver Binary Count output. (B) Quinary Counter output voltage levels after each clock count.
sufficiently negative that the left transistors continue to conduct. The voltage on the base of the right transistor in multi $E$ is at the 0 level, and the LO Binary Count input causes multi E to change state.

The change of state of multi $E$ changes the voltage across load resistors $A$ and $E$. The output voltage levels are now $A$, $0 ; B,-; C,+; D,-;$ and $E,+$. At the next Clock input (2), the Binary Count input goes HI. This tends to forward bias the left transistor in each multi, but causes only multi A to change state. The left transistors of multis $B$ and $D$ are already forward biased, and the right transistors of multis $C$ and $E$ are sufficiently forward biased to remain conducting.

This sequence of operation continues for the remainder of the Binary Count. The output voltage levels after each Clock input are shown in Fig. 3-7(B). The multi which has the 0-level output changes state at the next Clock input, and conditions the next multi.

Resistor networks connected between the multivibrator outputs compare the output voltage levels of the multis to provide a HI level on one of five output lines. The output line with the HI level indicates the quinary count to the $B C D$ Encoder. The resistor network consists of five pairs of resistors. Each pair of resistors compares the state of two adjacent multivibrators; R370-R399 compares $A$ and E, R367-R371 compares A and B, R373-R379 compares $B$ and C, R381-R387 compares C and D, and R389-R396
compares D and E. The outputs to the BCD Encoder are taken from the junction of each resistor pair. The level of an output line is HI only when the associated multivibrator output levels are + and 0 (or 0 and + ); other combinations result in zero or a LO output.

## BCD Encoder

BCD Encoder U420-U434 translates the Quinary Counter outputs to encode the $2^{1}, 2^{2}$, and $2^{3}$ bits of the $B C D$ output (the $2^{0}$ bit is encoded directly from the Binary Counter output).

The five Quinary Counter output lines are connected to the bases of five-transistor IC array U420. The transistor in this array which has the most positive base will conduct. When the base of $U 420 \mathrm{~B}, \mathrm{C}, \mathrm{D}$, or E is HI , the corresponding collector goes LO to provide an output to U434. The collector of U420A is grounded. Thus, when the base of U420A is HI ( $0-1$ count), U 420 conducts, but no output is provided. Three inverted-input OR gates within U434 provide the $2^{1}, 2^{2}$, and $2^{3}$ bits of the BCD output from the U420 outputs. An input/output table for U420-U434 is given in Fig. 3-8.

## Carry Comparator

The Carry Comparator provides the $\overline{\text { CARRY }}$ output to the second decade counter ( $10^{1}$ ) in the Counter and Readout Encoding circuit. The CARRY output is a HI to LO level transition to indicate the tenth Clock input counted by the First Decade Counter circuit (see Fig. 3-5, Input/ output table for the First Decade Counter circuit).

Emitter-coupled pair 0405-Q407 compares the voltage levels at the bases of Q392 and Q402 to compare the output levels of multivibrators $D$ and $E$. The transistor with the more positive base controls the conduction of Q405 or Q407. For Clock inputs five through nine, the more positive output level of multivibrator D will cause Q407 to conduct and Q405 to be cut off. As a result, the level at the collector of Q 405 is HI . At the tenth Clock input, the output level of multivibrator $E$ becomes more positive to turn on Q405. The collector of Q 405 goes LO. The HI to LO level transition at the collector of Q405 is applied to emitter-follower Q 418 to provide the $\overline{\text { CARRY }}$ output.

| Input | Outputs |  |  |  |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| HI Level | U420 |  |  |  | U434 |  |  |
| Quinary Counter | B | C | D | E | 21 | $2^{2}$ | $2^{3}$ |
| Output Line | Pin 5 | Pin 8 | Pin 11 | Pin 14 | Pin 6 | Pin 3 | Pin 8 |

Fig. 3-9. Counter circuit detailed block diagram.

## COUNTER CIRCUIT

## General

The Counter circuit consists of the Decade Counters, Storage Registers, Multiplexers, Overflow Register, ZeroCancel Logic, and the Time Slot Inverter stages. A detailed block diagram of the Counter circuit is shown in Fig. 3-9. A schematic of this circuit is shown on Diagram 3 in the Diagrams section.

The Decade Counters count the $\overline{C A R R \bar{Y}}$ output from the First Decade Counter circuit, and translate this count to a binary-coded-decimal (BCD) form. This BCD data, along with the First Decade Counter BCD output, is stored in the Storage Registers. Upon command of the DISPLAY input, the stored BCD data is transferred to the Multiplexers. When the Decade Counters have counted to 99999999, the counters are full. At the next count, the Decade Counters provide a HI to LO level transition FULL COUNT output to the Overflow Register.

The Overflow Register stores the $\overline{\text { FULL COUNT }}$ input, and provides the OVERFLOW output on command of the $\overline{\text { DISPLAY }}$ input. $\overline{\text { DCU RESET }}$ is applied to the Counter
circuit to reset the Decade Counters to the zero-count state and to reset the OVERFLOW output HI.

The time-slot pulses from the oscilloscope readout system are connected to the Counter circuit and to the Readout Encoding circuit through the Interface Connector. The time-slot pulses are inverted by the Time-Slot Inverters to provide time-slot data to the Multiplexers, Zero-Cancel Logic, and to the Readout Encoding circuit.

The BCD outputs of the Storage Registers are applied to the Multiplexers and Zero-Cancel Logic stages. The Multiplexers stage sequences the $B C D$ inputs to provide the Readout Encoding circuit with only four specific BCD bits at any one time. The sequencing is determined by the outputs of the Time-Slot Inverters to ensure proper placement of each digit in the readout display. The Zero-Cancel Logic stage provides zero-cancel logic outputs to the Readout Encoding circuit as determined by inputs from the Storage Registers, Overflow Register, and Time-Slot Inverter stages.

## Decade Counters

The $10^{1}$ through $10^{7}$ Decade Counters are seven cascaded divide-by-ten IC counters. Each decade translates the
decimal input to a BCD output for the corresponding Storage Register. The operation of each decade is similar. The counting operation is performed on a HI to LO transition at the T (trigger) input, pin 8. The DCU RESET input is connected to the direct-reset input (pin 13) of each counter. When the $\overline{D C U}$ RESET input goes LO, the Decade Counters are reset to the zero-count state. An input/output table applicable to each decade is given in Fig. 3-10.

The HI to LO transition of the $\overline{\mathrm{CARRY}}$ input triggers the $10^{1}$ Decade Counter U440. At the tenth CARRY input, pin 12 of U 440 goes from HI to LO to provide a trigger to the $10^{2}$ Decade Counter U442. The operation of the remainder of the decades is similar. The tenth input to the $10^{7}$ Decade Counter U452 triggers the counter from the nine-count to the zero-count. The $2^{3}$ output (pin 12) level goes from HI to LO to provide the FULL COUNT output to the Overflow Register (see Fig. 3-10).

|  | INPUT | OUTPUTS |  |  |  |
| :---: | :---: | :---: | :---: | :---: | :---: |
|  | $\begin{gathered} \hline \text { TRIGGER } \\ \text { Pin } 8 \end{gathered}$ | BCD |  |  |  |
|  |  | $\begin{gathered} 2^{0} \\ \operatorname{Pin} 5 \end{gathered}$ | $\begin{gathered} 2^{1} \\ \operatorname{Pin} 9 \end{gathered}$ | $\begin{gathered} 2^{2} \\ \text { Pin } 2 \\ \hline \end{gathered}$ | $\begin{gathered} 2^{3} \\ \text { Pin } 12 \end{gathered}$ |

|  | 9 | Hi | LO | LO | HI |

Fig. 3-10. Decade Counter input/output table.

## Storage Registers

The eight IC Storage Registers store the corresponding decade counter BCD output. The BCD input is applied to the D (data) inputs at pins $4,10,3$, and $11\left(2^{0}-2^{1}-2^{2}-2^{3}\right.$ bits respectively). The DISPLAY input is applied to the data-strobe input at pin 1 of each Storage Register IC. When the DISPLAY input goes LO, the logic levels at the D inputs are transferred to the associated BCD bit output to provide a $B C D$ output to the Readout Encoding circuit.

## Overflow Register

U508B is connected as an inverter. U508B inverts the HI to LO FULL COUNT input to provide a positive-going output to the $T$ input of U510A. U510A is an edge-triggered, D-type flip-flop with a direct-clear input. When U510A is triggered, the HI at the D -input is transferred to the 1 -output. A LO applied to the direct-clear input of U510A clears U510A for a LO output. DCU RESET is applied to the U510A direct-clear input. DISPLAY is applied to the base of Q512 through R511. Q512 inverts its input to provide the DISPLAY output to U504B and U504C.

When the Decade Counters are counting, $\overline{\mathrm{DCU}}$ RESET is HI and DISPLAY is HI (for most modes of operation). When the Decade Counters have reached a count of 99999999, the next count provides a HI to LO $\overline{\mathrm{FULL}}$ COUNT output to the input of U508B. U508B inverts the transition to provide a positive-going trigger to U510A. This triggers U510A to transfer the HI level at the D-input to the 1-output. When DISPLAY goes LO, Q512 provides a HI to U504B and U504C. U504B then provides a LO to the direct-clear input of U510B. This clears U510B for a LO level OVERFLOW output.

When DCU RESET goes LO, U510A is cleared for a LO 1 -output. This results in a HI U504B output. This HI applied to pin 9-U504C, and the HI level DISPLAY applied to pins 10 and 11 of U504C, results in a U504C LO output. This LO applied to the direct-set input of U510B at pin 10 sets U510B for a HI output.

## Multiplexers

The Multiplexers consist of eight IC's; U520, U524, U528, U532, U536, U540, U544, and U548. Each multiplexer IC is addressed by a particular time-slot input to provide the BCD data to encode the corresponding readout display digit. Each IC contains four two-input NAND gates. The inverted time-slot input is connected to one input of each NAND gate. A BCD bit input is applied to the remaining NAND gate input. The NAND gate outputs are connected to common $2^{0}-2^{1}-2^{2}-2^{3}$ output lines to the Readout Encoding circuit.

The Multiplexers invert the BCD outputs of the Storage Registers to drive the LO-true inputs of the Readout Encoding circuit. +5 volts is applied to each output line through resistor R555, R556, R557, or R558. Quiescently, this holds the output lines HI. When a HI level inverted time-slot pulse addresses a Multiplexer, a HI input level will result in a LO output; a LO input will result in no change or a HI output. For example, the $10^{0}$ Storage Register $2^{0}-2^{1}-2^{2}-2^{3}$ outputs for the decimal-digit three will be $\mathrm{HI}-\mathrm{HI}-\mathrm{LO}-\mathrm{LO}$ respectively. These input levels are applied to Multiplexer U520 at pins 6-12-2-8 respectively. When U520 is addressed by inverted time-slot TS-10, the U520 outputs will be $2^{0}-$ LO, $2^{1}-\mathrm{LO}, 2^{2}-\mathrm{HI}, 2^{3}-\mathrm{HI}$ at pins 4-13-1-10 respectively.

## Time-Slot Inverters

The Time-Slot Inverters invert the negative-going timeslot pulses to provide a HI -level pulse output for each input pulse. Each inverter consists of a single-transistor section of five-transistor arrays U531 or U541. Quiescently, each transistor is forward biased to saturation to hold the collector level close to ground. The time-slot pulse is connected to the inverter-transistor base through a zener diode to drop the pulse voltage level about 12 volts. This ensures that the -15 -volt time-slot input pulse almost reaches its negative extremity before the associated inverter-transistor is reverse biased. When the inverter transistor is reverse biased, the

Fig. 3-11. Logic diagram for Zero-Cancel Logic stage.
collector level goes HI to provide a HI -level time-slot output.

## Zero-Cancel Logic

The Zero-Cancel Logic stage provides logic level outputs during time-slots TS-3, TS-4, TS-5, and TS-6. A HI level output during any one of these four time-slots encodes the Readout Encoding circuit for a SPACE instruction. A LO level output allows the Readout Encoding circuit to encode the output for the decimal digit called for by the $B C D$ inputs.

A logic diagram of the Zero-Cancel Logic stage is shown in Fig. 3-11. The logic components are grouped according to the display digit which is directly affected by the corresponding Zero-Cancel Logic stage output. An input/ output table for each digit-group is shown in Fig. 3-12.

## READOUT ENCODING CIRCUIT

## General

A discussion entitled introduction to the Readout System following the 7D14 Circuit Description gives a brief description of the readout system used in Tektronix 7000-Series Oscilloscopes. Refer to this description for more information on operation of the readout system.

| Inputs |  |  | Outputs <br> 8th-Digit Zero-Cancel |

$\Phi$ Has no effect in this case
Fig. 3-12. Input/output table for Zero-Cancel Logic stage.

Fig. 3-13. Readout Encoding circuit detailed block diagram.

The 7D14 Readout Encoding circuit consists of the Digital-to-Analog (D-A) Converter, Over-range Indicator, MEASUREMENT INTERVAL Switch Logic, Decimal Logic, and Measurement Units Logic stages. The Readout Encoding circuit encodes the Channel 1 and 2, Row and Column output lines according to the format given in Table 3-1. A detailed block diagram of the Readout Encoding circuit is shown in Fig. 3-13. A schematic of this circuit is given on Diagram 4 in the Diagrams section.

Time-slot sequenced BCD data and zero-cancel logic outputs from the Counter circuit are applied to the D-A Converter stage. The D-A Converter encodes the Channel 1 outputs for time-slot three through time-slot ten (TS-3 through TS-10) as determined by the Counter circuit outputs. During TS-3, TS-4, TS-5, and/or TS-6 the D-A Converter can encode a SPACE instruction as determined by inputs from the Counter circuit (Zero-Cancel Logic). A SPACE instruction encoded in a time-slot results in a blank space for the corresponding digit position.

TABLE 3-1
7D14 READOUT ENCODING FORMAT

| Time-Slot <br> Number | Description |  |
| :--- | :--- | :--- |
|  | Channel 1 | Channel 2 |
| TS-1 | Determines decimal <br> position. | Encodes JUMP in- <br> struction in MANU- <br> AL GATE mode. |
| TS-2 | Encodes to indi- <br> cate ov er-range <br> measurement. | Not used. |
| TS-3 | Encodes most sig- <br> nificant (8th) digit <br> of measurement <br> (count) display, or <br> SPACE instruction. | Not used. |
| TS-4 | Encodes 7th digit of <br> count display, or <br> SPACE instruction. | Encodes M (mega-) <br> and (kilo-) pre- <br> fixes. |
| TS-5 | Encodes 6th digit of <br> count display, or <br> SPACE. | Encodes H. |
| TS-6 | Encodes 5th digit, or <br> SPACE. | Encodes z. |
| TS-7 | Encodes 4th digit. | Not used. |
| TS-8 | Encodes 3rd digit. | Not used. |
| TS-9 | Encodes 2nd digit. | Not used. |
| TS-10 | Encodes 1st digit. | Not used. |

Time-slot pulse TS-2 from the oscilloscope readout system is connected to the Over-Range Indicator stage. The Over-Range Indicator stage encodes the Channel 1 outputs for $>$ (greater then symbol) on command of the OVER. FLOW input.

The MEASUREMENT INTERVAL Switch Logic connects time-slot pulse TS-1 to the Decimal Logic stage or to the Measurement Units Logic stage. Also, the MEASUREMENT INTERVAL Switch Logic stage provides logic level outputs to indicate the switch setting to the previously mentioned stages and to the Time Base and Control circuit. The INTERNAL output to the Time Base and Control circuit indicates operation in the internal gate or MANUAL GATE modes.

The Decimal Logic stage encodes the Channel 1 outputs to determine the position of the decimal in the measurement display. The Measurement Units Logic stage encodes the Channel 2 outputs to display the proper measurement units or the JUMP instruction as determined by the MEASUREMENT INTERVAL Switch Logic outputs.

## Digital-to-Analog Converter

Digital-to-Analog (D-A) Converter U560 produces an output current which encodes the readout system Channel 1 Column output for time-slots TS-3 through TS-10. The level of this output current is determined by inputs from the Multiplexer, Time-Slot Inverters, and Zero-Cancel Logic stages. During time-slots TS-3 through TS-6, the output current encodes either decimal digits or a SKIP instruction as determined by the Zero-Cancel Logic inputs.

Fig. 3-14 shows the input and output configuration of U560. The output of U560 is a current into pin 15, shown

Fig. 3-14. Input and output configuration for U560.
as $I_{c}$ in Fig. 3-14. Resistors R563-R565-R566-R567-R568 between the 1 -inputs and -15 volts set the l -input currents at the levels shown in Fig. 3-14. A LO level applied to a D-(data) input directs the current set at the corresponding I -input to pin 15 to provide the $\mathrm{I}_{\mathrm{c}}$ output (e.g., LO at $\mathrm{D}^{0}$ directs $I_{0}$ current to pin 15). HI level TS-1 and TS-2 inputs to the E-input (enable) at pin 8 inhibit an output during these time-slots.
$B C D$ inputs to $U 560$ enable an $I_{C}$ analog output level which is 0.1 milliampere ( mA ) less than necessary to encode the desired decimal digit. A LO level applied to the $\mathrm{D}_{\mathrm{Z}}$-input at pin 1 directs the current set at the $\mathrm{I}_{\mathrm{Z}}$-input to pin 15 to add 0.1 mA to the $\mathrm{I}_{\mathrm{c}}$ output. The Time-Slot Inverter HI-level outputs during TS-7 through TS-10 are inverted by Q515 and applied to the $\mathrm{D}_{\mathrm{Z}}$-input. These inputs enable $U 560$ to produce an $I_{c}$ output as encoded by the $B C D$ inputs at these time-slots. Inputs to the $D_{z}$-input during time-slots TS 3 through TS-6 are determined by the inputs to the Zero-Cancel Logic stage (see the discussion of the Zero-Cancel Logic stage under Counter Circuit).

## Decimal Logic and Measurement Units Logic

These stages encode the readout system for decimal point position and measurement units as determined by MEASUREMENT INTERVAL switch S60.

MEASUREMENT INTERVAL Switch Logic. S60 provides logic level outputs to indicate the switch setting. The time-slot TS-1 input is switched through S60 to either the Decimal Logic or the Measurement Units Logic stage. S60 also provides the INTERNAL output to the Time Base and Control circuit. When this output is HI , internal gate ( 1 ms -10 s ) operation is indicated. When the INTERNAL output is LO, manual or external gate operation is indicated.

When one of the S60 internal gate buttons ( $1 \mathrm{~ms}-10 \mathrm{~s}$ ) is in, +5 volts applied through R660 provides a HI INTERNAL output level. A LO level (ground) is provided on one of five output lines to indicate which internal gate button is in. For example, if the 1 ms button is in, a LO $\overline{1}$ $\overline{\mathrm{ms}}$ output level is connected to CR655-CR676. TS-1 is connected through S 60 to the Decimal Logic stage under the internal gate condition.

When one of the MANUAL GATE buttons (ON-OFF) is in, R660 is connected to ground to hold the INTERNAL output LO. TS-1 is connected to the Measurement Units Logic stage to encode a JUMP instruction.

The $560 \overline{T \mathrm{~ms}}, 10 \mathrm{~ms}, 100 \mathrm{~ms}, ~ T \mathrm{~s}$, and 10 s outputs are applied to the Decimal Logic and Measurement Units Logic stages through diode-logic NOR gates. A simplified diagram of the diode-logic NOR gates, Decimal Logic, and Measurement Units Logic stages is shown in Fig. 3-15.

Decimal Logic. This stage encodes the Channel 1 Column and Row output current levels for time-slot one
(TS-1) to determine placement of the displayed decimal point. The level of the Column output current is determined by the inputs from the MEASUREMENT INTER. VAL Switch Logic. Also, decimal-logic Decimal Position Five and Decimal Position Six (DP-5 and DP-6) outputs are provided to the Zero-Cancel Logic stage. Q653, Q658, Q663, and Q670 are saturated due to the forward bias levels set at their bases by the resistor voltage dividers. This stage operates as follows:

When the $\overline{100 \mathrm{~ms}}$ input is LO, the other inputs are HI . This LO level reverse biases Q653; the collector is HI to provide the DP-5 output. At the same time, TS-1 interrogates R671-R659-R673-R674. The TS-1 current through R674 encodes the Row Current output for decimals. The TS-1 current through R673 encodes the Column Current output for decimal point location 5. The TS-1 current through R671 and R659 is sinked to ground through saturated transistors $\mathbf{Q 6 7 0}$ and 0658 respectively.

When the $\overline{10 \mathrm{~ms}}$ or $\overline{10 \mathrm{~s}}$ input is LO, the CR665-CR666 NOR-gate output is LO. This LO level reverse biases Q663 and Q 670 . The collector of Q 663 goes HI to provide the DP-6 output. Due to reverse bias, Q670 is cut off to allow the TS -1 current through R671 to be added to the Column Current output through CR671. This adds 0.1 mA to the TS-1 current through R673 to encode decimal point location 6.

Similarly, a LO $\overline{1 \mathrm{~ms}}$ or $\overline{\mathrm{s}}$ input reverse biases Q658 through diode NOR-gate CR656-CR655 to allow TS-1 current through R659 to pass through CR659. This adds 0.2 mA to the TS-1 current through R673 to encode decimal point location 7.

Measurement Units Logic. This stage encodes the Channel 2 Column and Row Current output levels for TS-4, TS-5, and TS-6. R686-R687 and R688-R689 encode the Column and Row Current outputs for TS-5 and TS-6 respectively (see Table 3-1, 7D14 Readout Encoding Format). R683-R684 set the Column and Row Current outputs for TS-4 to encode $k$ (kilo-prefix). When the $\overline{1 s}$ or $\overline{10}$ $\bar{s}$ input is LO, Q680 is saturated by the voltage level set at its base by voltage divider R677-R678-R679. The TS-4 current through R681 is sinked to ground through Q680. When the $1 \mathrm{~ms}, 10 \mathrm{~ms}$, or 100 ms input is LO, the output of diode-logic NOR gate CR676-CR677-CR678 is LO to reverse biase $\mathbf{Q} 680$. This allows the TS-4 current through R681 to add 0.1 mA to the Column Current output to encode an M (mega- prefix).

When TS-1 is applied to the Measurement Units Logic stage through S60 for MANUAL GATE operation (see MEASUREMENT INTERVAL Switch Logic), R682 encodes the Row Current output for a JUMP instruction ( 1.3 mA ).

Fig. 3-16. Time Base and Control circuit detailed block diagram.

## TIME BASE AND CONTROL CIRCUIT

## General

The Time Base and Control circuit generates the control signals described in the Control Signals discussion at the start of this section. A block diagram of the Time Base and Control circuit is shown in Fig. 3-16. This diagram shows the output signals produced by this stage and the basic interconnections between blocks. The interconnections shown are intended only to indicate interrelation between blocks; and do not indicate a direct connection, or that only a single connection is made between the given blocks. Details of the inter-relation between stages in this circuit are given in the circuit description which follows. A schematic of this circuit is shown on Diagram 5 in the Diagrams section.

## Switch Logic

The outputs from the Time Base and Control circuit determine the 7D14 measurement mode. These outputs are a function of the MEASUREMENT INTERVAL, REF FREO/CH B, RESET, and Manual Gate Storage switches. The relationship between these switches and the stages in the Time Base and Control circuit is as follows:

MEASUREMENT INTERVAL. In the 1 ms through 10 s switch position, the Gate Generator stage GATE output is controlled by one of the outputs of the Time Base Decade Counters stage. The switch position nomenclature (e.g., 1 ms ) refers to the GATE output "on" time resulting from a one-megahertz reference-frequency input. Also, in these positions the selected gate is connected to the MONITOR output connector through the Gate Buffer.

In the MANUAL GATE switch settings, the GATE output is controlled manually by the ON and OFF pushbuttons through the Manual/External Gate Input stage. When the OFF button is in, the GATE output can be controlled by an external gating signal connected to the EXT GATE input connector.

REF FREQ/CH B. In the INT 1 MHz position, the Divide By Five Counter one-megahertz output is connected to the Time Base Decade Counters and to the Reference Frequency Gate stage. Also, the Monitor Buffer onemegahertz output is provided to the MONITOR output connector.

When the EXT IN button is in, the EXT IN connector is connected to the Channel B Input Shaper stage; and, the Channel B Input Shaper output is provided to the Time Base Decade Counters and to the Reference Frequency Gate stage.

RESET. The RESET pushbutton, when pressed in, grounds an input to the Reset Input stage. This results in a HI RESET output. When the RESET button is released, the other input to the Reset Input stage is grounded. This results in a LO RESET output.

Manual Gate Storage. The Counter and Readout Encoding circuit INTERNAL output is connected to the Display Enable stage through the off position of the Manual Gate Storage switch. When the INTERNAL input is HI , the switch position has no effect on the Display Enable stage $\overline{\text { DISPLAY }}$ output. When the INTERNAL input is LO, it can be applied to the Display Enable stage through the off position of the Manual Gate Storage switch to hold the DISPLAY output LO.

Block Diagram Description. The $5-\mathrm{MHz}$ Oscillator is a temperature-compensated crystal oscillator. The $5-\mathrm{MHz}$ output is divided by the Divide by Five Counter stage to provide a one-megahertz output to the Monitor Output stage and to the REF FREQ/CH B switch.

The Channel B Input Shaper shapes and amplifies signals connected to the REF FREQ/CH B EXT IN connector when the EXT IN button is in.

The Time Base Decade Counters count the reference frequency selected by the REF FREQ/CH B switch, S50. This stage consists of seven cascaded decade counters. Outputs from the last five decade counters provide referencefrequency division ratios of $10^{3}, 10^{4}, 10^{5}, 10^{6}$, and $10^{7}$. These outputs are selected by the MEASUREMENT INTERVAL switch to provide a means of turning the Gate Generator on for precise time intervals. The time intervals selected are the reciprocal of the divided referencefrequency input. The MEASUREMENT INTERVAL switch pushbuttons are labelled according to the time interval selected for a one-megahertz reference-frequency input.

The Reset Input stage produces the RESET signal to the Gate Generator, Display Enable, and DCU RESET Driver stages on command of the front-panel RESET pushbutton or reset signal applied to the pin-jack connector.

The Manual/External Gate Input stage provides outputs to the Gate Generator to turn the GATE output on or off by means of the MEASUREMENT INTERVAL-MANUAL GATE pushbuttons, or by means of an external gate signal applied to the EXT GATE connector.

The Gate Generator stage generates the GATE control signal. The complementary GATE and GATE outputs are provided to several stages within the Time Base and Control circuit and to the Channel A Signal Conditioning circuit. The GATE "on" time is established by inputs from the Time Base Decade Counters, Reference Frequency Gate, and Manual/External Gate Input stages as determined by the MEASUREMENT INTERVAL switch. The GATE "on" time can be terminated by an input from the Reset Input stage. At the end of the GATE "on" time, a CLEAR output is provided to the Display Enable stage. Also, an output is provided to the Lamp Driver to illuminate the GATE indicator lamp when the GATE is "on".

The Display Enable stage produces the LO level $\overline{\text { DIS }}$ $\overline{\text { PLAY }}$ output as determined by the inputs to this stage. The INTERNAL input is applied to this stage in the off position of the Manual Gate Storage switch. When the INTERNAL input is HI , the setting of the Manual Gate Storage switch has no effect on the operation of this stage. The Display Enable stage will produce the DISPLAY output on command of the Gate Generator CLEAR output, or on command of the Reset Input stage RESET output.

When the INTERNAL input is LO and the Manual Gate Storage switch is in the off position, the DISPLAY output is held LO. When the INTERNAL input is LO and the Manual Gate Storage switch is in the on position, the DIS$\overline{\mathrm{PLAY}}$ output is produced on command of the other inputs as mentioned previously.

The Display Generator stage produces an output at a time after the end of the GATE "on" time as determined by the DISPLAY TIME control setting. The Display Generator output is amplified by the DCU RESET Driver stage to provide the DCU RESET output. Also, the DCU RESET Driver stage produces the $\overline{\mathrm{DCU}}$ RESET output on command of the Reset Input stage RESET output signal.

## 5 MHz Oscillator

The 5 MHz Oscillator, Y600, provides a precise fivemegahertz output. An internal adjustment provides a means of setting the oscillator frequency. The five-megahertz output is connected to the Divide by Five Counter stage.

## Divide by Five Counter

The Divide by Five Counter stage consists of IC U602. The five-megahertz input is applied to the $T$ (trigger) input at pin 6. The counting operation is performed on the negative-going transition at the T input. The one-megahertz output at pin 12 is provided to the Reference Frequency Gate when the REF FREQ/CH B switch is in the INT 1 MHz position, and to the Monitor Buffer stage. In the EXT IN position of the REF FREQ/CH B switch, a LO level (ground) is applied to the direct-clear input of $U 602$ at pin 13. This LO holds the output LO.

## Monitor Buffer

The Monitor Buffer stage consists of Q606. This stage amplifies the one-megahertz output of the Divide by Five Counter stage. The Monitor Buffer output is connected to the REF FREQ/CH B MONITOR output connector when the REF FREQ/CH B switch is in the INT 1 MHz position.

## Channel B Input Shaper

The Channel B Input Shaper shapes and amplifies signals connected to the REF FREQ/CH B EXT IN connector when the EXT IN button is pressed.

The signal connected to the EXT IN connector is ACcoupled to the base of Q613 through C610, R610, and C611. Q613 and Q618 make up an emitter-coupled bistable multivibrator. The multivibrator shapes the input signal to provide a square-wave output to Q623 through R621-C621. Q623 amplifies the square-wave signal. The output at the collector of Q623 is connected to ground when the INT 1 MHZ button is in, or connected to U729E when the EXT IN button is in.

## Reference Frequency Gate

The Reference Frequency Gate stage consists of NANDgate U731D and isolation-transistor U729E. The referencefrequency signal selected by the REF FREQ/CH B switch is applied to one input of the NAND gate through U729E. The INTERNAL input is connected to the other NANDgate input. When INTERNAL is $\mathrm{HI}(1 \mathrm{~ms}$ through 10 s positions of the MEASUREMENT INTERVAL switch), the reference-frequency signal is provided from the NAND-gate output (pin 11) to the T-input of U735 in the Gate Generator stage.

## Time Base Decade Counters

The Time Base Decade Counters count the input selected by the REF FREQ/CH B switch, S50, and applied to pin 8-U628 (trigger). The counters consist of seven cascaded divide-by-ten counters, U628-U630-U632-U634-U636-U638-U640.

Each decade is clocked with a negative-going transition applied to the $T$ input, pin 8 . With the exception of U628, each decade is clocked only when the output of the preceding decade changes from HI to LO.

The $\overline{\text { DCU RESET input to pin 13-U628 and pin } 1 \text { of the }}$ remaining decades reset the counters for an output of 9999990; i.e., pin $12-\mathrm{U} 640$ through U630 is HI , and pin 12-U628 is LO.

## Reset Input

The Reset Input stage provides an input to the Time Base and Control circuit from the RESET pushbutton and pin-jack connector. When the RESET button is pressed in, or when a HI level is applied to the base of $\mathbf{Q} 703$ through the pin-jack connector, a HI level RESET output is set at pin 13-U708D. When the RESET button is released, or a LO level is applied to the base of Q703, the output at pin 13-U708D returns LO. Q738 inverts the HI RESET level to provide a LO level to the direct-clear input of U735 in the Gate Generator stage.

## Manual/External Gate Input

RS flip-flop U708A-U708B, in conjunction with Q714-Q742-U729A-U729B, provides outputs to the Gate

Generator to turn the GATE output "on" or "off" as determined by the MANUAL GATE pushbuttons or by an external gating signal applied to the EXT GATE input connector.

This stage provides a LO output to the direct-clear input of U735 at pin 14 to turn the Gate Generator GATE output "off", or a LO output to the direct-set input of U735 at pin 10 to turn the GATE output "on".

The INTERNAL input is applied to the base of Q714 through R717, and to the base of U729B through CR722-R722. When either of the MANUAL GATE pushbuttons is in, the INTERNAL input is LO. The levels at the inputs and outputs of U708A-U708B and at the collector of 0742 for the MANUAL GATE ON and OFF pushbutton settings are shown in Fig. 3-17. When the collector of 0742 is LO, the GATE is "on" and when U708B-pin 4 is LO, the GATE is "off".

When the MANUAL GATE OFF button is in, the EXT GATE input connector is connected to the base of Q714 through R716-C716. A HI level applied to the EXT GATE connector is inverted by Q714 to provide a LO to U708B at pin 5 . This will cause the level at U708B-pin 4 to go HI. This LO to HI transition is coupled to the base of U729A through C743 to momentarily turn U729A on. The collector of U729A goes LO to provide an output to the directset input of U735. When the input to the EXT GATE connector goes LO, the collector of 0714 goes HI. As a result, the level at U708B-pin 4 goes LO to provide a clear command to the direct-clear input of U735.

The INTERNAL input is HI when the MEASUREMENT INTERVAL switch is set to one of the internal-gate positions, 1 ms through 10 s . This HI level inhibits the Manual/ External Gate Input stage by applying forward bias to saturate U729B through CR722-R722 and 0714 through R717. Due to saturation, the collectors of 0714 and U729B are LO. The LO at the collector of 0714 holds U708B-pin 5 LO. This results in a HI level output at U708B-pin 4. The LO at the collector of U729B applies reverse bias to U729A to keep its collector HI. As a result, U735 is not affected by the Manual/External Gate Input stage under this condition.

| MANUAL <br> GATE | U708A-U708B |  |  | 0742 |
| :---: | :---: | :---: | :---: | :---: |
|  | Pin 5 | Pin 2 | Pin 4 | Collector |
| ON | LO | HI | HI | LO |
| OFF | HI | LO | LO | HI |

Fig. 3-17. Manual/External Gate Input stage input and output levels for MANUAL GATE operation.

## Gate Generator

The Gate Generator stage includes three J-K flip-flops with direct-set and direct-clear inputs. U735 generates the GATE and GATE output signals. Inputs to U735, U733A, and U733B determine the state of the GATE signal. The Gate Generator stage outputs are provided by two emittercoupled transistor pairs, Q751-Q753 and Q758-Q763. These transistor pairs isolate the $\mathbf{U 7 3 5}$ outputs from the circuits being driven, and also provide signal gain.

U733A is connected as an RS flip-flop. The 1 -output (pin 11) is connected to the U733B J-input and to the Display Generator stage (U729D). The 0-output (pin 10) is connected to the Manual/External Gate Input stage through R724.

The $\overline{D C U}$ RESET signal (produced by U731A) is coupled through C783-R783 to the base of Q781. When the $\overline{\mathrm{DCU}}$ RESET input goes HI , the LO to HI transition momentarily turns on Q781 to pull its collector LO. This LO applied to the U733A direct-set input (pin 7) sets U733A for a HI 1 -output.

At the end of the GATE "on" time, a LO CLEAR command is provided to the U733A direct-clear input (pin 8). This clears U733A to provide a LO 1-output.

Triggered J-K flip-flop U733B is clocked by the Time Base Decade Counters output to turn the Gate Generator GATE output "on" for the gate time selected by the MEASUREMENT INTERVAL switch. The U733B 1- and 0 -outputs set the levels at the $\cup 735 \mathrm{~J}$ - and K - inputs respectively. An input/output table applicable to U733B or U735 is shown in Fig. 3-18.

The level at the U733B J-input is the U733A 1 -output level. The level at the U733B K-input is the U733B 1 -output level. The LO $\overline{\mathrm{DCU}} \mathrm{RESET}$ input to the directclear input clears U733B for a LO 1-output level.

| Inputs |  | Outputs |  |
| :---: | :---: | :---: | :---: |
|  |  | Condition after trigger pulse |  |
| $J$ | K | 1 | 0 |
| LO | LO | No change |  |
| LO | HI | LO | HI |
| HI | LO | HI | LO |
| HI | HI | Changes state |  |

A LO input to the direct-set input sets the 1 output HI . A LO input to the direct-clear input sets the 1 output LO.

Fig. 3-18. Input/output table for U733B or U735.

After a LO DCU RESET input to the direct-clear input, U733B 1- and 0-outputs are LO and HI respectively. The J-input is HI (U733A is set by DCU RESET); the K-input, connected to the 1 output, is LO. The next HI to LO transition at the $T$ (trigger) input sets the 1 and 0 outputs of U733B to be HI and LO respectively. The J- and Kinputs are now both HI . The next HI to LO transition at the T-input will toggle U733B.

Triggered J-K flip-flop U735 generates the GATE signal as determined by the inputs. The GATE is "on" when the U735 1 -output ( $\operatorname{pin} 9$ ) is HI and the 0 -output (pin 7) is LO. U735 is triggered on the negative-going transition of the Reference Frequency Gate stage (U731D) output applied to the T -input. When triggered, the output changes states in response to the levels set at the J - and K -inputs prior to the trigger.

When the J - and K -inputs are set HI and LO respectively by the U733B outputs, the next negative-going transition of the Reference Frequency Gate stage output will trigger U735 to set the 1 -output HI to turn the GATE "on". When the J - and K -inputs are set LO and HI respectively, the next negative-going transition at the $T$ input will set the 1 output LO to turn the GATE "off".

A LO applied to the direct-set input over-rides the J-, K-, and T -inputs to set the 1 -output HI (GATE "on"). A LO applied to the direct-clear input over-rides the J-, K-, and T-inputs to set the 1 -output LO (GATE "off").

A LO applied to the direct-set input from the Manual/ External Gate Input stage (U729A or P742) will turn the GATE "on". A LO to the direct-clear input from the Manual/External Gate Input stage (U708B) or from the Reset Input stage ( 0738 ) will turn the GATE "off".

The U735 1- and 0-outputs are connected to the bases of Q751 and Q753 through R750 and R754 respectively. Q751 and Q753 translate the logic levels at the U735 outputs to provide the GATE and GATE outputs to the Channel A Signal Conditioning circuit through T755. 0751 and Q753 invert the U735 outputs so that the GATE output is HI with respect to GATE when the GATE is "on".

The GATE and $\overline{\text { GATE }}$ signals are also connected to Q763 and Q758 respectively. Q758 and Q763 invert the Q751-Q753 outputs to provide logic levels corresponding to the GATE "on" and "off" states to other Time Base and Control circuit stages. When the Gate is "on", the collector of Q758 provides a HI output to the Display Generator (U729D), and to the Lamp Driver (Q776) to turn on the GATE indicator light (DS80). When the GATE is "on", the collector of Q763 is LO. When the GATE is turned off, the

LO to HI transition at the collector of Q 763 is coupled through C765-R765 to momentarily turn on Q768. The collector of Q768 goes LO to provide a LO CLEAR output.

## Display Enable

The Display Enable stage consists of inverter transistor U729C, inverted-input NOR gate U731B, and NAND gate U731C. This stage produces the LO DISPLAY output when a LO is applied to either input of U731B.

When the INTERNAL input is LO, and the Manual Gate Storage switch is in the off position, the DISPLAY output is held LO. When the INTERNAL input is HI, or the Manual Gate Storage switch is in the on position, the output is determined by the level applied to U731B-pin 5. Quiescently, +5 volts applied to U731B-pin 5 through R768 holds pin 5 HI .

The Gate Generator CLEAR output (at the collector of Q768) is connected directly to U731B-pin 5. When CLEAR goes LO, U731B-pin 8 goes LO to provide the DISPLAY output. The Reset Input stage RESET signal is connected to the base of U729C through R772. When RESET is HI, the collector of U729C is LO. This results in a LO DISPLAY output.

## Display Generator

The Display Generator provides a positive pulse output to the DCU RESET Driver through R794. This pulse is generated by relaxation oscillator Q791, a unijunction transistor. U729D acts as a three-input NOR gate to inhibit Q791. A HI level is applied to the base of U729D through CR786 when the DISPLAY TIME control is set to $\infty$ or through R759 when the GATE is on to inhibit Q791. When the DISPLAY TIME control is not set to $\infty$, the Display Generator is enabled when the GATE ends and U733A is cleared (the 1 -output is LO). The LO applied to the base of U729D when all inputs are LO reverse biases U729D to allow C 788 to charge to a positive level sufficient to forward bias Q791. DISPLAY TIME R70 adjusts the RC timeconstant of R70-R789-C788 to set the time required to charge C788 to a level which will switch on 0791 . When C788 charges positive enough to forward bias Q791, it dis. charges through Q791, R793, and L793 to generate a positive pulse output across L793.

## DCU RESET Driver

The DCU RESET Driver, Q796-0798-U731A, provides the DCU RESET output to the First Decade Counter circuit, Counters and Readout Encoding circuit, and to several stages within the Time Base and Control Circuit. The positive-going pulse input from the Display Generator or a HI level input from the Reset Input stage applied to the
base of $\mathrm{Q} 7 \underline{96}$ is amplified and inverted by this stage to provide the $\overline{\text { DCU RESET output. }}$

## INTRODUCTION TO THE READOUT SYSTEM

## Introduction

The following discussion is provided to acquaint the 7D14 user with the Readout System employed in Tektronix 7000 -Series Oscilloscopes. Since the oscilloscope Readout System provides the digital readout for the 7D14, it is necessary to relate the function of the 7D14 to the Readout System to gain a better understanding of the 7D14 operation. A detailed circuit description of the 7000 -series Readout System is given in the oscilloscope instruction manual.

## The Readout System

The Readout System in the 7000 -series oscilloscopes provides alpha-numeric display of information encoded by the plug-in units. This display is presented on the CRT and
is written by the CRT beam on a time-shared basis with the analog waveform display.

The Readout System produces a pulse train consisting of ten negative-going pulses called time-slots. These pulses represent a possible character in a readout word, and each is assigned a time-slot number corresponding to its position in the word. Each time-slot pulse is directed to one of ten output lines, labelled TS-1 through TS-10 (time-slots one through ten), which are connected to the vertical and horizontal plug-in compartments. Two output lines, row and column, are connected from each channel (two channels per plug-in compartment) back to the Readout System.

Data is encoded on these output lines either by connecting resistors between them and the time-slot input lines or by generating equivalent currents. The resultant output is a sequence of analog current levels on the row and column output lines. The row and column current levels are decoded by the Readout System to address a character matrix during each time-slot, thus selecting a character to be displayed or a special instruction to be followed.

# SECTION 4 MAINTENANCE 

Change information, if any, affecting this section will be found at the rear of this manual.

## Introduction

This section of the manual contains maintenance information for use in preventive maintenance, corrective maintenance, and troubleshooting of the 7D14.

Further maintenance information relating to component color codes and soldering techniques can be found in the instruction manuals for the 7000 -series oscilloscopes.

## PREVENTIVE MAINTENANCE

## General

Preventive maintenance, consisting of cleaning, visual inspection, lubrication, etc., performed on a regular basis, will improve the reliability of this instrument. Periodic checks on the semiconductor devices used in the unit are not recommended as a preventive maintenance measure. See semiconductor-checking information given under troubleshooting.

## Cleaning

Avoid the use of chemical cleaning agents which might damage the plastics in this instrument. Avoid chemicals containing benzene, toluene, xylene, acetone, or similar solvents.

Front Panel. Loose dust may be removed with a soft cloth or a dry brush. Water and mild detergent may be used; however, abrasive cleaners should not be used.

Interior. Cleaning the interior of the unit should precede calibration, since the cleaning process could alter the settings of the calibration adjustments. Use low-velocity compressed air to blow off the accumulated dust. Hardened dirt can be removed with a soft, dry brush, cotton-tipped swab, or cloth dampened with a mild detergent and water solution.

## Lubrication

Use a cleaning-type lubricant on shaft bushings, interconnecting plug contacts, and switch contacts. Lubricate switch detents with a heavier grease. A lubrication kit containing the necessary lubricating materials and instructions is available through any Tektronix Field Office. Order Tektronix Part No. 003-0342-00.

## Recalibration

To ensure accurate measurements, the 7D14 should be checked after each 1000 hours of operation or every six months if used infrequently. A complete performance check procedure is given in Part I of Section 5.

The performance check procedure can be helpful in isolating major troubles in the unit. Moreover, minor troubles not apparent during regular operation may be revealed and corrected.

## TROUBLESHOOTING

## General

The following is provided to augment information contained in other sections of this manual for use in troubleshooting the 7D14. The schematic diagrams, Circuit Description, and Calibration sections should be used to full advantage. The Circuit Description section gives detailed information on circuit behavior and output requirements.

## Troubleshooting Aids

Diagrams. Circuit diagrams are given on foldout pages in Section 7. The circuit number and electrical value of each component in this instrument are shown on the diagrams. Important voltages are also shown.

Circuit Boards. The circuit boards used in the 7D14 are outlined on the schematic diagrams, and a photograph of each board is shown on the back of the circuit diagram foldout pages. Each board-mounted electrical component is identified on the photograph by its circuit number.

Component and Wiring Color Code. Colored stripes or dots on resistors and capacitors signify electrical values, tolerances, etc., according to the EIA standard color code. Components not color coded usually have the value printed on the body.

The insulated wires used for interconnection in the 7D 14 are color coded to facilitate tracing a wire from one point to another in the unit.

Semiconductor Lead Configuration. Fig. 4-1 shows the lead configuration of the semiconductor devices used in this instrument.

## Troubleshooting Equipment

The following equipment is useful for troubleshooting the 7D 14:

1. Semiconductor Tester-Some means of testing the transistors, diodes, and FET's used in this instrument is helpful. A transistor-curve tracer such as the Tektronix Type 576 will give the most complete information.
2. DC Voltmeter and Ohmmeter-A voltmeter for checking voltages within the circuit and an ohmmeter for checking resistors and diodes are required.
3. Test Oscilloscope-A test oscilloscope is required to view waveforms at different points in the circuit.

A Tektronix 7000-series Oscilloscope with 7D13 Digital Multimeter unit, 7B-series Time-Base unit, and a 7A-series Amplifier unit with a 10X probe will meet the needs for items 2 and 3.

## Troubleshooting Procedure

This troubleshooting procedure is arranged in an order which checks the simple trouble possibilities before proceeding with extensive troubleshooting.

1. Check Control Settings. Incorrect settings of the 7D14 controls can indicate a trouble that does not exist. If there is any question about the correct function or operation of a control or front-panel connector, see the Operating Instructions section.
2. Check Associated Equipment. Before proceeding with troubleshooting of the 7D14, check that the equipment used with this instrument is operating correctly. If possible,
substitute a 7D14 known to be operating correctly into the indicator unit and see if the problem persists. Check that the inputs are properly connected and that the interconnecting cables are not defective.
3. Visual Check. Visually check the portion of the instrument in which the trouble is suspected. Many troubles can be located by visual indications, such as unsoldered connections, broken wires, damaged circuit boards, damaged components, etc.
4. Check Instrument Performance. Check the calibration of the unit, or the affected circuit by performing Part I Performance Check of Section 5. The apparent trouble may only be a result of misadjustment and may be corrected by calibration. Complete calibration instructions are given in Part II of Section 5.
5. Check Voltages and Waveforms. Often the defective component or stage can be located by checking for the correct voltage or waveform in the circuit. Typical voltages and waveforms are given on the diagrams; however, these are not absolute and may vary slightly between instruments. To obtain operating conditions similar to those used to take these readings, see the instructions in the Diagrams section.
6. Check Individual Components. The following methods are provided for checking the individual components in the 7D14. Components which are soldered in place are best checked by disconnecting one end to isolate the measurement from the effects of surrounding circuitry.
A. TRANSISTORS AṄD INTEGRATED CIRCUITS. The best check of transistor and integrated circuit operation is actual performance under operating conditions. If a transistor or integrated circuit is suspected of being defective, it can best be checked by substituting a component known to be good; however, be sure that circuit conditions are not such that a replacement might also be damaged. If substitute transistors are not available, use a dynamic tester (such as Tektronix Type 576). Static-type testers may be used, but since they do not check operation under simulated operating conditions, some defects may go unnoticed. Fig. 4-1 shows base pin and socket arrangements of semiconductor devices. Be sure the power is off before attempting to remove or replace any transistor or integrated circuit.

Integrated circuits can be checked with a voltmeter, test oscilloscope, or by direct substitution. A good understanding of the circuit description is essential to troubleshooting circuits using integrated circuits. Use care when checking voltages and waveforms around the integrated cir-
cuits so that adjacent leads are not shorted together. An integrated-circuit test clip provides a convenient means of clipping a test probe to the 14 - and 16 -pin integrated circuits. This device also doubles as an integrated-circuit extraction tool.
B. DIODES: A diode can be checked for an open or shorted condition by measuring the resistance between terminals. With an ohmmeter scale having an internal source of between 800 millivolts and 3 volts, the resistance should be very high in one direction and very low when the leads are reversed.

Do not use an ohmmeter scale that has a high internal current. High currents may damage the diodes.
C. RESISTORS. Check resistors with an ohmmeter. Resistor tolerance is given in the Electrical Parts List. Resistors normally do not need to be replaced unless the measured value varies widely from the specified value.
D. CAPACITORS. A leaky or shorted capacitor can be detected by checking resistance with an ohmmeter on the highest scale. Use an ohmmeter which will not exceed the voltage rating of the capacitor. The resistance reading should be high after initial charge of the capacitor. An open capacitor can best be detected with a capacitance meter, or by checking whether the capacitor passes AC signals.
7. Repair and Readjust the Circuit. Special techniques required to replace components in this unit are given under Component Replacement. Be sure to check the performance of any circuit that has been repaired or that has had any electrical components replaced. Recalibration of the affected circuit may be necessary.

## REPLACEMENT PARTS

## Standard Parts

All electrical and mechanical part replacements for the 7D14 can be obtained through your local Tektronix Field Office or representative. However, many of the standard electronic components can be obtained locally in less time than is required to order them from Tektronix, Inc. Before purchasing or ordering replacement parts, check the parts list for value, tolerance, rating, and description.

## NOTE

When selecting replacement parts, it is important to remember that the physical size and shape of the
component may affect its performance in the instrument. All replacement parts should be direct replacements unless it is known that a different component will not adversely affect the instrument performance.

## Special Parts

Some parts are manufactured or selected by Tektronix to satisfy particular requirements, or are manufactured for Tektronix to our specifications. These special parts are indicated in the parts list by an asterisk preceding the part number. Most of the mechanical parts used in this instrument have been manufactured by Tektronix. Order all special parts directly from your local Tektronix Field Office or representative.

## Ordering Parts

When ordering replacement parts from Tektronix, Inc., refer to the Parts Ordering Information and Special Notes and Symbols on the page immediately preceding the Electrical Parts List section. Include the following information:

1. Instrument type (7D14)
2. Instrument Serial Number
3. A description of the part (if electrical, include the circuit number).

## 4. Tektronix Part Number

## COMPONENT REPLACEMENT

## General

The exploded-view drawings associated with the Mechanical Parts List may be helpful when disassembling or re-assembling individual components or sub-assemblies.

## Circuit Board Replacement

In general, the circuit boards used in the 7D14 need never be removed unless they must be replaced. Electrical connections to the boards are made by multiple-pin connectors (multi-pin connectors) and interconnecting pins. If it is necessary to replace a circuit board assembly, use the following procedure.

## A. HIGH FREQUENCY COUNTER CIRCUIT BOARD REPLACEMENT.

1. Disconnect the two multi-pin connectors from the circuit board.
2. Remove all the screws holding the board to the chassis or other mounting surface.
3. Using a 7/16-inch open-end wrench, loosen the nut securing the coaxial-cable connector to the rear of the CH A INPUT BNC connector.
4. Slide the nut over the coaxial-cable connector toward the circuit board.
5. Remove the board from the unit while sliding the coaxial-cable connector from the BNC connector.
6. To replace the board, first install the coaxial-cable connector in the BNC connector.
7. Position the board so the securing-screw holders mate with the guide posts.
8. Gently press the circuit board while making sure that all of the interconnecting pins and sockets mate properly.
9. Uniformly tighten the securing screws. Recommended torque, four to six inch-pounds.
10. Tighten the nut on the rear of the CH A INPUT connector.

## B. LOGIC AND CONTROL CIRCUIT BOARD REPLACEMENT.

1. Remove the High Frequency Counter circuit board following the procedure given under $A$.
2. Remove the springs and metal shield from the securing-screw guide posts.
3. Disconnect the multi-pin connectors from the circuit board.
4. Remove all the screws holding the board to the chassis or other mounting surface.
5. Remove the screws holding the plastic plug-in guide to the top and bottom frame sections.
6. Remove the board from the unit and from the plastic guide. Do not force or bend the board.
7. To replace the board, reverse the order of removal.

## Switch Replacement

Two types of switches are used in the 7D14, pushbutton and rotary. If a switch is defective, it must be replaced as a unit. Observe normal soldering precautions when replacing these switches. See the information under Light-Bulb Replacement for instructions on replacing the light bulbs. Illustrations of the pushbutton switches and the wiring color code are given on the backs of pull-out pages in the Diagrams section. Use the following procedures to replace a front-panel switch:

## A Pushbutton Switch Replacement

1. Remove the knobs from the LEVEL/SLOPE, INPUT SENS, and DISPLAY TIME control shafts. Use a $1 / 16$-inch hex-key wrench.
2. Remove the front panel from the instrument.
3. Disconnect the associated multi-pin connector(s) from the circuit board.
4. Remove the defective unit.
5. Disconnect the wires from the switch circuit board.
6. To replace, reverse the order of removal.

## B Rotary Switch Replacement

1. Before replacing the defective unit, draw a sketch of the terminals showing the wire color code to each terminal.
2. Disconnect the wires from the terminals.
3. Remove the knob from the control shaft. Use a 1/16-inch hex-key wrench.
4. Remove the defective unit from the instrument.
5. To replace, reverse the order of removal.

## CAUTION

When disconnecting or connecting leads to a wafertype rotary switch, do not let solder flow around and beyond the rivet on the switch terminal. Excessive solder can destroy the spring tension of the contact.

## Light-Bulb Replacement

The pushbutton switches contain one or more incandescent light bulb. To replace a defective light bulb, use the following procedure:

1. Remove the switch from the instrument as instructed under Switch Replacement. It is not necessary to remove the wires from the switch circuit board.
2. Clip off the bulb leads near the bulb body.
3. Remove the defective bulb from the plastic holder.
4. Remove the leads from the circuit board. Use a 15watt pencil-type soldering iron.
5. Remove the excess solder from the circuit board with a vacuum-type desoldering tool.
6. Install the replacement bulb so the bulb is centered in the plastic holder.
7. Solder the leads to the circuit board.
8. Replace the switch in the instrument.

## Transistor and Integrated Circuit Replacement

Transistors and IC's should not be replaced unless they are actually defective. If removed from their sockets during routing maintenance, return them to their original sockets. Special care must be given to integrated circuit leads, because they can easily be damaged in removal from sockets. Unnecessary replacement or switching of components may affect the calibration of the instrument. When a transistor is replaced, check the operation of the part of the instrument that may be affected.

## Recalibration After Repair

After any electrical component has been replaced, the calibration of that particular circuit should be checked, as well as the calibration of other closely related circuits. The Performance Check instructions given in Part I of Section 5 provide a quick and convenient means of checking the instrument operation. The Adjustment procedure in Part II of Section 5 can then be used to adjust the operation to meet the Performance Requirements listed in Section 1.

# SECTION 5 CALIBRATION 

Change information, if any, affecting this section will be found at the rear of this manual.

## Recalibration Interval

To assure instrument accuracy, check the calibration of the 7D14 every 1000 hours of operation, or every six months if used infrequently. Before complete calibration, thoroughly clean and inspect this instrument as outlined in the Maintenance section.

## Tektronix Field Service

Tektronix, Inc. provides complete instrument repair and recalibration at local Field Service Centers and the Factory Service Center. Contact your local Tektronix Field Office or representative for further information.

## Using This Procedure

General. This section provides several features to facilitate checking or adjusting the 7D14. These are:

Index. To aid in locating a step in the Performance Check or Adjustment procedure, an index is given preceding Part I - Performance Check and Part II - Adjustment procedure.

Performance Check. The performance of this instrument can be checked without removing the side shields or making internal adjustments by performing only Part I Performance Check. This procedure checks the instrument against the tolerances listed in the Performance Requirement column of Section 1. In addition, a cross-reference is provided to the step in Part 11 - Adjustment, which will return the instrument to correct calibration. In most cases, the adjustment step can be performed without changing control settings or equipment connections.

Adjustment Procedure. To return this instrument to correct calibration with the minimum number of steps, perform only Part II - Adjustment. The Adjustment procedure gives the recommended calibration procedure for all circuits in this instrument.

Partial Procedure. A partial check or adjustment is often desirable after replacing components or to touch up the adjustment of a portion of the instrument between major recalibrations. To check or adjust only part of the instrument, start with the nearest Equipment Required list pre-
ceding the desired portion. To prevent unnecessary recalibration of other parts of the instrument, readjust only if the tolerance given in the CHECK- part of the step is not met. If re-adjustment is necessary, also check the calibration of any steps listed in the INTERACTION-part of the step.

Complete Performance Check/Adjustment. To completely check and adjust all parts of this instrument, perform both Parts I and II. Start the complete procedure by performing the Adjustment procedure for a portion of the instrument (e.g., Channel A Adjustments) and follow this with the Performance Check for the same portion (e.g., Channel A Checks). This method will assure that the instrument is both correctly adjusted and performing within all Performance Requirements as given in Section 1.

## TEST EQUIPMENT REQUIRED

## General

The following test equipment and accessories, or its equivalent, is required for complete calibration of the 7D14. Specifications given for the test equipment are the minimum necessary for accurate calibration. Therefore, some of the specifications listed here may be somewhat less precise than the actual performance capabilities of the test equipment. All test equipment is assumed to be correctly calibrated and operating within the listed specifications.

The Performance Check and Adjustment procedures are based on this recommended equipment. If other equipment is substituted, control settings or calibration setup may need to be altered to meet the requirements of the equipment used. Detailed operating instructions for the test equipment are not given in this procedure. Refer to the instruction manual for the test equipment if more information is needed.

## Calibration Equipment Alternatives

All of the test equipment is required to completely check and adjust this instrument. However, some of the items used only for the Performance Check can be deleted without compromising the instrument's measurement capabilities. For example, the pulse generator is used only in the Performance Check and may be deleted if the user does not desire to check the performance of the External Gate or External Reset functions. Equipment used only for

## Calibration-7D14

the Performance Check procedure is indicated by note ${ }^{1}$; items required only for the Adjustment procedure are indicated by note ${ }^{2}$.

## Test Equipment

1. 7000 -series oscilloscope equipped with a readout system, referred to as the Indicator Oscilloscope in this procedure. For example, a Tektronix 7504 Oscilloscope.
2. Amplifier plug-in unit, Tektronix 7A16.
3. Time-Base plug-in unit, Tek tronix 7B70.
4. Frequency standard. Any frequency standard calibrated to the National Bureau of Standards transmissions. Frequency, one megahertz; accuracy, within 0.05 part per million; long term drift, one part or less in $10^{8}$ per month.
5. High-frequency constant-amplitude sine-wave generator. Frequency, variable from 120 to 500 megahertz; reference frequency, three megahertz; output amplitude, variable from 50 millivolts to 4.5 volts; amplitude accuracy, within $3 \%$ at three megahertz and within $5 \%$ at 500 megahertz. For example, Tektronix calibration fixture 067-0532-01.
6. Medium-frequency constant-amplitude sine-wave generator. Frequency, variable from 3.6 to 8.0 megahertz; reference frequency, 50 kilohertz; output amplitude, variable from 0.5 volt to five volts peak to peak into 50 ohms; amplitude accuracy, output amplitude constant within 3\% at 50 kilohertz and from 3.6 to 8.0 megahertz. For example, Tektronix Type 191 Constant Amplitude Signal Generator.
7. Low-frequency constant-amplitude signal generator. ${ }^{1}$ Frequency range, two hertz to two megahertz; amplitude, 0.5 volt to five volts peak to peak; amplitude accuracy. constant within $3 \%$ as output frequency changes. For example, General Radio Model 1310-B Oscillator.
8. Pulse Generator. ${ }^{1}$ Pulse period, 700 nanoseconds (ns); pulse width, variable from 200 ns to 500 ns ; maximum risetime and falltime, 500 ns ; trigger, internal or manual; output amplitude, variable from two to three volts. For example, Tektronix Type 115 Pulse Generator.

[^1]9. Time-Mark Generator. ${ }^{1}$ Marker outputs, one millisecond to one second; sine-wave output, two nanaoseconds; trigger output, one microsecond; marker accuracy, within $0.1 \%$. For example, Tektronix Type 2901 Time-Mark Generator.
10. Square-Wave Generator. Frequency, one kilohertz; output amplitude, variable from zero to 500 millivolts into 50 ohms. For example, Tektronix Type 106 Square-Wave Generator.
11. Digital Voltmeter. ${ }^{2}$ Range, zero to 10 volts; input impedance, 10 megohms or greater; accuracy, with in $0.1 \%$. For example, Tektronix 7D13 Digital Multimeter Plug-In Unit.
12. Flexible Plug-In Extender. ${ }^{2}$ Tektronix Part Number 067-0616-00.
13. Probe, 10X attenuation. ${ }^{2}$ Tektronix P6053.

## Accessories

14. BNC $T$ connector. ${ }^{1}$ Tektronix Part No. 103. 0030-00.
15. In line termination (two each). ${ }^{1}$ Impedance, 50 ohms; accuracy, $\pm 2 \%$; connectors, BNC. Tektronix Part No. 011-0049-01.
16. In-line termination. Impedance, 50 ohms; wattage rating, two watts; accuracy, $\pm 2 \%$; connectors, GR874 input with BNC male output. Tektronix Part No. 017-0083-00.
17. Adapter. Adapts GR874 connector to BNC male connector. Tektronix Part No. 017-0064-00.
18. Adapter. ${ }^{1}$ Adapts BSM male connector to BNC female connector. Tektronix Part No. 103-0036-00.
19. Attenuator. Impedance, 50 ohms; attenuation ratio, 10X; connectors, GR. Tektronix Part No. 017-0078-00.
20. Attenuator. ${ }^{2}$ Impedance, 50 ohms; attenuation ratio, 2X; connectors, GR. Tektronix Part No. 017. 0080-00.
21. Cable (two each). ${ }^{1}$ Impedance, 50 ohms; type, RG-58/U; length, 42 inches; connectors, BNC. Tektronix Part No. 012-0057-01.
22. Cable. ${ }^{1}$ Impedance, 50 ohms; type, RG-58/U; length, 18 inches; connectors, BNC. Tektronix Part No. 012-0076-00.
23. Cable. Impedance, 50 ohms; type, RG-213/U; length, five nanoseconds; connectors, GR. Tektronix Part No. 017-0512-00.
24. Cable. Pin-jack. ${ }^{1}$ Tektronix Part No. 175-1178-00.

## Adjustment Tools

25. Screwdriver. ${ }^{2}$ Three-inch shaft; 3/32-inch wide bit for slotted screws. For example, Xcelite R3323.
26. Tuning tool. ${ }^{2}$ Handle for 003-0310-00 and 003-0334-00 inserts. Tektronix Parts No. 003-0307-00.
27. Tuning-tool insert. ${ }^{2}$ For variable capacitors. Tektronix Part No. 003-0334-00.
28. Tuning-tool insert. ${ }^{2}$ For $5 / 64$-inch (ID) hex cores. Tek tronix Part No. 003-0310-00.

## Preliminary Control Settings

Set the controls as follows (for both Performance Check and Adjustment procedure):

## Indicator Oscilloscope

| A Intensity | Midrange <br> Focus |
| :--- | :--- |
| Adjust for well-defined |  |
| display |  |

7D14
MEASUREMENT INTERVAL 100 ms DISPLAY TIME 0.1 s REF FREQ/CH B INT 1 MHz TRIGGER PRESET
LEVEL/SLOPE Centered on positive slope
INPUT SENS $1 \mathrm{M} \Omega / 100 \mathrm{mV}$
BW $\quad 525 \mathrm{MHz}$
COUPLING

Any controls not mentioned can be set as desired.

## NOTES

## PART I-PERFORMANCE CHECK

## Introduction

The following procedure checks the performance of the 7D14 without removing the side shields or making internal adjustments. All tolerances given in this procedure are based on Section 1 of this manual.

## Index to Part I - Performance Check

Channel A Checks

1. Check CH A INPUT Frequency Range

Page 5-5
2. Check CH A INPUT $50 \Omega$ Sensitivity and Low-Frequency Range (AC-COUPLING)
3. Check CH A INPUT $1 \mathrm{M} \Omega$ Sensitivity and Low-Frequency Range
4. Check TRIG SOURCE Sensitivity 5-6
5. Check BW-5 MHz
6. Check Trigger LEVEL Range and SLOPE Selection

## Measurement Interval Checks

7. Check Crystal Oscillator Accuracy

Page 5-8
8. Check Internal Gate Range
9. Check Channel B Frequency Range and Sensitivity
10. Check External Gate $\quad 5-9$
11. Check Manual Gate 5-10
12. Check External Reset 5-10

## Output Signals Checks

13. Check INT 1 MHz Output

Page 5-11
14. Check Internal Gate Time Mark Output 5-11
15. Check Trigger Indicator

5-11

## Preliminary Procedure for Performance Check

## NOTE

The performance of this instrument can be checked at any temperature within the $0^{\circ} \mathrm{C}$ to $+50^{\circ} \mathrm{C}$ range unless stated otherwise.

1. Install the 7D14 in the B horizontal plug-in compartment of the Indicator Oscilloscope.
2. Connect the Indicator Oscilloscope to a power source which meets the frequency and voltage requirements of the oscilloscope power supply.
3. Turn the Indicator Oscilloscope power on. Allow at least twenty minutes warmup for checking the 7D14 to the given accuracy.
4. Set the controls as given under Preliminary Control settings.
5. Advance the Indicator Oscilloscope Readout control to obtain a usable readout display. Adjust the Focus and Astigmatism controls as necessary for well-defined characters in the display.

## CHANNEL A CHECK

## Equipment Required

1. Indicator Oscilloscope
2. Amplifier unit
3. Time-base unit
4. High-frequency constant-amplitude sine-wave generator
5. Medium -frequency constant-amplitude sine-wave generator
6. Low-frequency constant-amplitude sine-wave generator
7. GR 50 -ohm in-line termination
8. GR to BNC male adapter
9. 5-nanosecond GR cable
10. 42-inch BNC cable
11. 18-inch BNC cable
12. BNC T connector
13. GR 10X attenuator

## Control Settings

Set the controls as given under Preliminary Control Settings.

## NOTE

In steps one through four, the exact reading obtained depends on the accuracy of the generator dial setting.

## 1. Check CH A INPUT Frequency Range

a. Connect the high-frequency constant-amplitude sinewave generator to the amplifier unit input through the fivenanosecond GR cable, $10 \times$ GR attenuator, and 50 -ohm in-line termination, in given order.
b. Set the amplifier unit for a vertical deflection factor of 50 millivolts/division.
c. Set the high-frequency generator for a two-division $(100 \mathrm{mV}$ ) display at the $3-\mathrm{MHz}$ reference frequency.
d. Disconnect the 50 -ohm in-line termination from the amplifier unit input, and reconnect it to the CH A INPUT connector.
e. Set the high-frequency generator for a $500-\mathrm{MHz}$ output.
f. CHECK-The readout display should show a steady count of about 500.00000 MHz . Change the dial setting if necessary to obtain a count of at least 500 MHz .

## NOTE

This procedure checks the 7D14 frequency range to 500 MHz . To check the frequency range to the maximum limit as given under Performance Requirement in Section 1, use a constant-amplitude generator with at least a $525-\mathrm{MHz}$ output.
g. Set the INPUT SENS switch to $50 \Omega / 100 \mathrm{mV}$.
h. Replace the 50 -ohm in-line termination on the highfrequency generator output with a GR to BNC male adapter, and reconnect the generator to the CH A INPUT connector.
i. CHECK-The readout display for the same count obtained in part $f$ of this step (at least 500 MHz ).
j. Disconnect all test equipment.

## 2. Check CH A INPUT $50 \Omega$ Sensitivity and LowFrequency Range (AC-COUPLING)

a. Change the following control settings:

7D14
INPUT SENS $50 \Omega / 1 \mathrm{~V}$
MEASUREMENT INTERVAL 1 s
b. Connect the low-frequency constant-amplitude generator to the amplifier unit input connector through the 42inch BNC cable and BNC T connector. Connect the output
of the BNC T connector to the CH A INPUT through the 18 -inch BNC cable.
c. Set the amplifier unit for a vertical deflection factor of .2 volts/division.
d. Set the low-frequency generator for a five-division display (1 volt) at 200 kHz .
e. CHECK-Readout display for a steady count at about 200 kHz.
f. Press the COUPLING switch AC button.
g. CHECK-Readout display for the same count obtained in part e of this step.
h. Set the low-frequency generator for a five-division display (1 volt) at 10 kHz .
i. CHECK-Readout display for zero count $(0.000$ to 0.001 kHz ).

## 3. Check CH A INPUT 1 M $\Omega$ Sensitivity and LowFrequency Range

a. Change the following control settings:

## 7D14

| INPUT SENS | $1 \mathrm{M} \Omega / 1 \mathrm{~V}$ |
| :--- | :--- |
| COUPLING | DC |

b. CHECK-Readout display for a steady count at about 10 kHz .
c. Set the INPUT SENS switch to $1 \mathrm{M} \Omega / 10 \mathrm{~V}$ and the amplifier unit for a vertical deflection factor of 2 volts/ division.
d. Set the low-frequency generator for a five-division display ( 10 volts) at 10 kHz .
e. CHECK-Readout display for a steady count at about 10 kHz .
f. Set the low-frequency generator for a five-division display ( 10 volts) at 5 Hz .
g. Press the COUPLING switch AC button.
h. CHECK-Readout display for a steady count at about $5 \mathrm{~Hz}(0.005 \mathrm{kHz})$.

## 4. Check TRIG SOURCE Sensitivity

a. Change the following control settings:

7D14
INPUT SENS TRIG SOURCE COUPLING
b. Set the low-frequency generator for a 1.5 -division display ( 3 volts) at 10 kHz .
c. CHECK-Readout display for a steady count at about 10 kHz .
d. Disconnect all test equipment.

## 5. Check BW-5 MHz

a. Install the 7D14 in the left vertical plug-in compart ment of the Indicator Oscilloscope.
b. Change the following control settings:

Indicator Oscilloscope
Vertical Mode Chop

7D14
INPUT SENS $\quad 50 \Omega / 100 \mathrm{mV}$
BW 5 MHz
c. Connect the medium-frequency constant-amplitude generator to the CH A INPUT connector through the fivenanosecond GR cable, GR to BNC male adapter, and BNC T connector. Connect the output of the BNC T connector to the amplifier unit input through the 18 -inch BNC cable.

[^2]e. Set the medium-frequency generator for a fivedivision ( 100 millivolts) display at the $50-\mathrm{kHz}$ reference frequency.
f. Set the time-base unit for a sweep rate of $10 \mu \mathrm{~s} /$ division and observe the Trigger Indicator square-wave display.
g. Set the generator for an output of 3.5 MHz .
h. Increase the output frequency of the generator until the Trigger Indicator display amplitude becomes zero (a straight line).
i. CHECK-Output frequency of generator must be 5 $\mathrm{MHz} \pm 1 \mathrm{MHz}$.
j. Disconnect all test equipment.

## 6. Check TRIGGER LEVEL Range and SLOPE Selection

a. Change the following control settings:

7D14
COUPLING
AC
TRIGGER
VAR
LEVEL/SLOPE
Centered on positive slope (left of center)
b. Connect the medium-frequency constant-amplitude generator to the CH A INPUT through the five-nanosecond GR cable, GR to BNC male adapter, and BNC T connector. Connect the output of the BNC T connector to the amplifier unit input through the 18 -inch BNC cable.
c. Set the amplifier unit for a vertical deflection factor of $.2 \mathrm{volt} / \mathrm{division}$.
d. Set the generator for a five-division display ( 1 volt) of a $50-\mathrm{kHz}$ signal.
e. Set the time-base unit for a sweep rate of $20 \mu \mathrm{~s} /$ division.
f. Set the time-base unit to trigger at the center of the positive-slope region.
g. Rotate the 7D14 LEVEL/SLOPE control throughout the positive-slope range from the $6: 00$ o'clock to $12: 00$ o'clock positions while observing the Trigger Indicator and sine-wave generator displays.
h. CHECK-Trigger Indicator and sine-wave generator waveforms are in phase with one another (both waveforms start on the positive-going slope), and the Trigger Indicator display amplitude becomes zero (straight line) before the LEVEL/SLOPE control reaches either extreme of rotation.
i. Rotate the 7D14 LEVEL/SLOPE control throughout the negative-slope range from the 6:00 o'clock to 12:00 o'clock positions while observing the Trigger Indicator and sine-wave generator displays.
j. CHECK-Trigger Indicator and sine-wave generator waveforms are out of phase (sine-wave generator waveform starts on the positive slope and Trigger Indicator waveform starts on the negative slope), and the Trigger Indicator display amplitude becomes zero (straight line) before the LEVEL/SLOPE control reaches either extreme of rotation.
k. Disconnect all test equipment.

## NOTES

## MEASUREMENT INTERVAL CHECK

## Equipment Required

1. Indicator Oscilloscope
2. Amplifier unit
3. Time-base unit
4. Frequency standard
5. Low-frequency constant-amplitude sine-wave generator
6. Time-mark generator
7. Pulse generator
8. 42 -inch BNC cable (two required)
9. 18 -inch BNC cable
10. 50 -ohm BNC in-line termination (two required)
11. $B S M$ to $B N C$ female adapter
12. Pin-jack cable
13. BNC T connector

## Control Settings

Set the controls as given under Preliminary Control Settings.

## 7. Check Internal Crystal Oscillator Accuracy

a. Connect the 7D14 REF FREQ/CH B MONITOR connector to the amplifier unit input through the BSM to BNC female adapter, 18 -inch BNC cable, and 50 -ohm BNC termination.
b. Connect the marker output of the time-mark generator to the Indicator Oscilloscope high-sensitivity Z-axis input through the 42 -inch BNC cable and 50 -ohm BNC termination.
c. Set the time-mark generator for one-second markers.
d. Connect the frequency standard one-megahertz output to the time-base unit external trigger input connector.
e. Set the time-base unit for a sweep rate of $.5 \mu \mathrm{~s} /$ division externally triggered on the frequency-standard signal.
f. Set the Indicator Oscilloscope intensity control as necessary to observe the one-second intensity modulation of the CRT display.
g. CHECK-CRT display; the movement of the INT 1 MHz markers across the CRT should not exceed one division in one second.
h. CALIBRATION-See step 6 of the Adjustment procedure.
i. Disconnect all test equipment.

## 8. Check Internal Gate Range

a. Change the following control settings:

7D14

| MEASUREMENT INTERVAL | 1 ms |
| :--- | :--- |
| REF FREQ/CH B | EXT IN |
| INPUT SENS | $50 \Omega / 1 \mathrm{~V}$ |
| COUPLING | AC |

b. Connect the marker output of the time-mark generator to the 7D14 CH A INPUT through the 42 -inch BNC cable.
c. Connect the trigger output of the time-mark generator to the REF-FREQ/CH B EXT IN connector through the 42 -inch BNC cable, 50 -ohm BNC termination, and BSM to BNC female adapter, in given order.
d. Set the time-mark generator for two-nanosecond markers and one microsecond triggers.
e. CHECK-Sequentially press the MEASUREMENT INTERVAL 1 ms through 10 s buttons, and check the readout display for a count within the limits given in Table 5-1 for each button pressed.
f. Disconnect all test equipment.

TABLE 5-1

| MEASUREMENT <br> INTERVAL | Readout Limits |  |
| :---: | :---: | :---: |
|  | Minimum | Maximum |
| 1 ms | 499.999 MHz | 500.001 MHz |
| 10 ms | 499.9999 MHz | 500.0001 MHz |
| 100 ms | 499.99999 MHz | 500.00001 MHz |
| 1 s | 99999.999 kHz | 00000.001 kHz |
| 10 s | 9999.9999 kHz | 0000.0001 kHz |

## 9. Check Channel B Frequency Range and Sensitivity

a. Change the following control settings:

7D14
MEASUREMENT INTERVAL 1 s INPUT SENS $\quad 50 \Omega / 100 \mathrm{mV}$ BW 5 MHz
b. Connect the time-mark generator marker output to the 7D14 CH A INPUT through the 42 -inch BNC cable.
c. Set the time-mark generator for one-millisecond markers.
d. Connect the low-frequency constant-amplitude generator to the REF FREO/CH BEXT IN connector through the 42 -inch BNC cable, 50 -ohm BNC termination, BNC T connector, and BSM to BNC female adapter. Connect the output of the BNC T connector to the amplifier unit input through the 18 -inch BNC cable.
e. Set the amplifier unit for a vertical deflection factor of 0.2 volt/division and the time-base unit for a sweep rate of $0.2 \mu \mathrm{~s} / \mathrm{division}$ with internal triggering.
f. Set the low-frequency generator for a four-division display at two megahertz.
g. CHECK-The GATE indicator light should blink on and off, and the readout display should show a count of about 0.500 MHz .
h. Change the following control settings:

7D14

```
MEASUREMENT INTERVAL 1 ms
DISPLAY TIME }\infty\mathrm{ (infinite)
```

i. Set the time-base unit for a sweep rate of 0.5 second/ division.
j. Set the low-frequency generator for a four-division display ( 0.8 volt) at 10 hertz.
k. Press the RESET button to turn off the GATE indicator and reset the readout display to zero count.
I. CHECK-Release the RESET button; the GATE indicator should light and remain on for about one and one-half minutes.
m. CHECK-Readout display for a count of about 100.000 MHz .
n. Disconnect all test equipment.

## 10. Check External Gate

a. Change the following control settings.

7D14

| MEASUREMENT INTERVAL | MANUAL GATE OFF |
| :--- | :--- |
| REF FREQ/CH B | INT 1 MHz |
| BW | 525 MHz |
| DISPLAY TIME | 0.1 s (counterclockwise) |

b. Connect the pulse generator (Type 115) output to the amplifier unit input through the 42 -inch BNC cable and 50 -ohm BNC termination.
c. Set the pulse generator controls as follows:

| Period | 100 ns |
| :--- | :--- |
| Width | 50 ns |
| Risetime and Falltime | 10 ns |
| Mode | Undly'd Pulse |
| Trigger | Int |
| Pulse Polarity | + |
| DC Offset | Preset |
| Amplitude | 1.0 |

d. Set the pulse generator variable amplitude control for a three-division display.

[^3]

Fig. 5-1. Pulse generator output waveform for checking external gate operation.
f. Set the pulse generator variable width control for a two-division positive-pulse width (measure the pulse width where the positive-pulse amplitude is two divisions, as shown in Fig. 5-1).
g. Disconnect the 50 -ohm BNC termination from the amplifier unit input and connect it to the EXT GATE input connector through the BSM to BNC female adapter.
h. Connect the marker output of the time-mark generator to the CH A INPUT through the 42 -inch BNC cable.
i. Set the time-mark generator for 2 nanosecond markers.
j. CHECK-Readout display for a count of $0100 \pm 15$ counts (0085 to 0115).
k. Disconnect all test equipment.

## 11. Check Manual Gate

a. Change the following control settings:

7D14
DISPLAY TIME $\infty$ (infinite)
b. Connect the marker output of the time-mark generator to the CH A INPUT through the 42 -inch BNC cable,

50 -ohm BNC termination, and BNC T connector. Connect the output of the T connector to the amplifier unit input through the 18 -inch BNC cable.
c. Set the time-base unit for a sweep rate of two seconds/division.
d. Set the time-mark generator for one-second markers.
e. Momentarily press the RESET button.
f. Press the MANUAL GATE ON button, count ten time marks on the CRT; then press the MANUAL GATE OFF button.
g. CHECK-Readout display for a count of $0010 \pm 1$ count (0009 to 0011).
h. Disconnect all test equipment.

## 12. Check External Reset

a. Set the time-base unit for a sweep rate of $0.1 \mu \mathrm{~s} /$ division.
b. Connect the pulse generator output to the amplifier unit input through the 42 -inch BNC cable and 50 -ohm BNC termination.
c. Set the pulse generator output amplitude for a twodivision display.
d. Set the pulse generator for a five-division positive pulse width.
e. Set the pulse generator for manual trigger operation.
f. Disconnect the $50-\mathrm{ohm}$ BNC termination from the amplifier unit input and connect it to the RESET pin-jack connector through the pin-jack cable.
g. Momentarily press the pulse generator manual trigger button.
h. CHECK-Readout display for zero count $\pm 1$ count ( 0000 to 0001).
i. Disconnect all test equipment.

## OUTPUT SIGNALS CHECKS

## Equipment Required

1. Indicator Oscilloscope
2. Amplifier plug-in unit
3. Time-base plug-in unit
4. Medium-frequency constant-amplitude sine-wave generator
5. Five-nanosecond GR cable
6. 50 -ohm in-line termination
7. 18-inch BNC cable
8. BNC T connector
9. BSM to BNC male adapter

## Control Settings

Set the controls as given under Preliminary Control Settings.

## 13. Check INT 1 MHz Output

a. Set the amplifier unit for a vertical deflection factor of 1 volt/division and the time-base unit for a sweep rate of $0.5 \mu \mathrm{~s} /$ division.
b. Connect the REF FREQ/CH B MONITOR output to the amplifier unit input through the BSM to BNC female adapter and 18 -inch BNC cable.
c. CHECK-CRT display for vertical deflection of five divisions $\pm 0.5$ division.
d. Disconnect the cable and adapter.

## 14. Check Internal Gate Time Mark Output

a. Change the following control settings:

## 7D14

MEASUREMENT INTERVAL 1 ms
b. Connect the MEASUREMENT INTERVAL MONITOR output to the amplifier unit input through the BSM to BNC female adapter and 18 -inch BNC cable.
c. Set the time-base unit for a sweep rate of $0.2 \mathrm{~ms} /$ division.
d. CHECK-CRT display for vertical deflection of five divisions $\pm 0.5$ division. Positive gate duration should be about five divisions.
e. Disconnect the cable and adapter.

## 15. Check Trigger Indicator

a. Change the following control settings:

Vertical Mode | Indicator Oscilloscope |
| ---: |
| Chop |

b. Set the amplifier unit for a vertical deflection factor of 0.1 volt/division and the time-base unit for a sweep rate of $0.5 \mathrm{~ms} /$ division.
c. Connect the medium-frequency constant-amplitude sine-wave generator to the CH A INPUT through the fivenanosecond GR cable, 50 -ohm in-line termination, and BNC T connector. Connect the output of the $T$ connector to the amplifier unit input through the 18 -inch BNC cable.
d. Set the medium-frequency generator for a fourdivision display ( 0.4 volt) at 50 kHz .
e. Center the sine-wave display with the amplifier unit Position control.
f. CHECK-Trigger Indicator display (square wave) for vertical deflection of 0.2 division $\pm 0.05$ division.
g. Disconnect all test equipment.

This completes the Performance Check of the 7D14.

## PART II-ADJUSTMENT

## Introduction

The following procedure returns the 7D14 to correct calibration. All limits and tolerances given in this procedure are calibration guides, and should not be interpreted as instrument specifications except as listed in the Performance Requirement column in Section 1. The actual operation of the instrument may exceed the given limits or tolerances if the instrument meets the Performance Requirements as checked in Part I - Performance Check of this section.
Index of Part II - AdjustmentChannel A Adjustments

1. Adjust Input Zero (R225) ..... Page 5-13
2. Adjust Trigger Preset (R125) ..... 5-13
3. Adjust Low-Frequency Compensation (C132)4. Adjust Reference Voltage (R320)5-14
4. Adjust High-Frequency Compensation ..... 5-15(C150)
Measurement Interval Adjustment
5. Adjust Crystal Oscillator Frequency
Output Signal Adjustment
6. Adjust Trigger Indicator Display Posi- ..... 5-17

## Preliminary Procedure for Adjustment

## NOTE

This instrument should be adjusted at an ambient temperature of $25^{\circ} \mathrm{C} \pm 5^{\circ} \mathrm{C}$ for best overall accuracy.

1. Remove the right side shield from the 7D14, and the right side panel from the Indicator Oscilloscope.
2. Install the 7D14 in the B horizontal plug-in compartment of the Indicator Oscilloscope.
3. Connect the Indicator Oscilloscope to a power source which meets the frequency and voltage requirements of the oscilloscope power supply.
4. Turn the Indicator Oscilloscope power on. Allow at least twenty minutes warmup before proceeding.
5. Set the controls as given under Preliminary Control Settings.
6. Advance the Indicator Oscilloscope Readout control to obtain a usable readout display. Adjust the Focus and Astigmatism as necessary to obtain a well-defined display.

## NOTE

Titles for external controls of this instrument are capitalized in this procedure (e.g., INPUT SENS). Internal adjustments are initial capitalized only (e.g., Ref Voltage).

## NOTES

## CHANNEL A ADJUSTMENTS

## Equipment Required

| 1. Indicator Oscilloscope | 8. $10 \times$ probe |
| :--- | :--- |
| 2. Amplifier unit | 9. Five-nanosecond GR cable |
| 3. Time-base unit | 10. 50 -ohm in-line termination |
| 4. Digital voltmeter | 11. GR to BNC male adapter |
| 5. Square-wave generator | 12. $10 \times \mathrm{GR}$ attenuator |
| 6. High-frequency constant-amplitude sine-wave generator | 13. $2 \times$ GR attenuator |
| 7. Medium-frequency constant-amplitude sine-wave  <br> generator 14. Tuning tool and inserts | 15. Three-inch screwdriver |

## Control Settings

Set the controls as given under Preliminary Control Settings.

## Location of Adjustments and Test Points

The locations of the Channel A Adjustments and Test Points are shown in Fig. 5-2.

## 1. Adjust Input Zero

a. Set the INPUT SENS control to $50 \Omega / 100 \mathrm{mV}$.
b. Connect the digital voltmeter between test point 118 and chassis ground.
c. CHECK - Voltmeter reading; zero volt $\pm 0.001$ volt.
d. ADJUST-Zero adjustment R225 for a voltmeter reading of exactly zero volt.

## 2. Adjust Trigger Preset

a. Change the following control settings:

Fig. 5-2, Location of Channel A Adjustments and Test points forn right side of instrumentl.

## Indicator Oscilloscope

Horizontal Mode
A
b. Set the amplifier unit for a vertical deflection factor of $50 \mathrm{mV} /$ division and the time-base unit for a sweep rate of $0.1 \mu \mathrm{~s} /$ division.
c. Connect the medium-frequency constant-amplitude sine-wave generator to the amplifier unit input through the five-nanosecond GR cable and 50 -ohm in-line termination.
d. Set the medium-frequency generator for a threedivision display at three megahertz.
e. Disconnect the 50 -ohm in-line termination from the amplifier unit input and from the five-nanosecond GR cable. Connect the five-nanosecond GR cable to the CH A INPUT connector through the GR to BNC male adapter.
f. Set the amplifier unit for $A C$ input coupling at a vertical deflection factor of $5 \mathrm{mV} /$ division.
g. Connect the 10X probe to the amplifier unit input.
h. Connect the 10X probe tip to test point 254 and connect the probe ground to chassis ground.
i. Center the CRT display with the amplifier unit position control.
j. CHECK-CRT display for the trigger switching points to be centered on the sine wave as shown in Fig. 5-3.
k. ADJUST-Preset adjustment R125 to center the trigger switching points on the sine-wave display.
I. CHECK-Digital voltmeter reading; zero volt $\pm 0.001$ volt.
m. ADJUST-Zero adjustment R225 for a voltmeter reading of exactly zero volt.
n. Repeat parts i and j of this step.
o. Disconnect all test equipment.

Fig. 5-3. Trigger switching points on sine-wave display.

## 3. Adjust Low-Frequency Compensation

a. Set the time-base unit for a sweep rate of $0.2 \mathrm{~ms} /$ division. Set the time-base unit to trigger at the center of the negative-slope region.
b. Connect the 10X probe to the amplifier unit input.
c. Connect the probe tip to test point 254 and connect the probe ground to chassis ground.
d. Connect the square-wave generator +output to the CH A INPUT through the five-nanosecond GR cable and GR to BNC male adapter.
e. Set the square-wave generator for a five-division display at one kilohertz.
f. CHECK-CRT display; overshoot on square-wave display should not exceed 0.25 division.
g. ADJUST-C132 for optimum square wave with overshoot not exceeding 0.25 division.
h. Disconnect all test equipment.

## 4. Adjust Reference Voltage

a. Change the following control settings:

7D14
MEASUREMENT INTERVAL 1 ms
b. Set the amplifier unit for a vertical deflection factor of $50 \mathrm{mV} /$ division.
c. Connect the high-frequency constant-amplitude sinewave generator to the amplifier unit input through the fivenanosecond GR cable, $10 \times$ GR attenuator, and 50 -ohm in-line termination.
d. Set the high-frequency generator for a two-division display at the $3-\mathrm{MHz}$ reference frequency.
e. Disconnect the high-frequency generator from the amplifier unit input.
f. Connect the generator to the CH A INPUT through the five-nanosecond GR cable, 10X GR attenuator, and GR to BNC male adapter.
g. Set the high-frequency generator for a 120 -megahertz output.
h. CHECK-Readout display for a steady count of about 120 MHz .
i. Connect the digital voltmeter between test point 326 and chassis ground.
j. Adjust the Ref Voltage adjustment R320 as far clockwise as possible without significantly changing the $120-\mathrm{MHz}$ count; note the voltmeter reading.
k. Adjust the Ref Voltage adjustment R320 as far counterclockwise as possible without significantly changing the $120-\mathrm{MHz}$ count; note the voltmeter reading.
I. ADJUST-Ref Voltage adjustment R320 for a voltmeter reading halfway between the readings obtained in
parts i and j of this step. For example, if the upper voltmeter reading is -3.70 volts and the lower voltmeter reading is -2.90 volts, the difference between the two is -0.80 volt. Adjust R320 for the lower reading plus one-half the difference or -3.30 volts.
m . Disconnect all test equipment.

## 5. Adjust High-Frequency Compensation

a. Set the amplifier unit for a vertical deflection factor of 10 mV /division.
b. Connect the high-frequency generator to the amplifier unit input through the five-nanosecond GR cable, 10X GR attenuator, $2 X$ GR attenuator, and 50 -ohm in-line termination.
c. Set the high-frequency generator for a five-division ( 50 millivolts) display at the $3-\mathrm{MHz}$ reference frequency.
d. Disconnect the generator from the amplifier unit input.
e. Connect the generator to the CH A INPUT through the five-nanosecond GR cable, 10X GR attenuator, $2 \times \mathrm{GR}$ attenuator, and GR to BNC male adapter.
f. Set the generator for a $500-\mathrm{MHz}$ output.
g. Check-Readout display for a count of about 500 MHz .
h. ADJUST-C150 for a $500-\mathrm{MHz}$ count.
i. Disconnect all test equipment.
j. Replace the Indicator oscilloscope right cover.

## MEASUREMENT INTERVAL ADJUSTMENT

## Equipment Required

1. Indicator oscilloscope
2. Flexible plug-in extender

## Control Settings

Set the controls as given under Preliminary Control Settings.

The location of the Measurement Interval adjustment is shown in Fig. 5-4.

## 6. Adjust Crystal Oscillator Frequency

## NOTE

The oscillator frequency must be adjusted at an ambient room temperature of about $+25^{\circ} \mathrm{C}$ according to the following procedure to ensure operation within the limits given in Section 1 for an operating temperature range of $0^{\circ} \mathrm{C}$ to $+50^{\circ} \mathrm{C}$.
a. Remove the 7D14 from the Indicator Oscilloscope.

Fig. 5-4. Location of Measurement Interval and Output Signal Adjustments \{on left side of instrumentl.
3. Frequency standard
4. Tuning tool
b. Replace the right side shield on the unit and remove the left shield.
c. Note the Frequency at $27^{\circ} \mathrm{C}$ notation on the crystal oscillator cover (see Fig. 5-4).
d. Place the 7D14 on the flexible plug-in extender and plug the extender into the Indicator Oscilloscope.
e. Connect the frequency standard one-megahertz output to the CH A INPUT.
f. Press the MEASUREMENT INTERVAL 10 s button and the BW 5 MHz button.
g. Place the 7D14 with the left side on the bench so the crystal oscillator is facing downward. Allow the unit to warm up in this position for about 15 minutes.
h. CHECK-Readout display for a count of 1000.0000 $\mathrm{kHz} \pm$ one-fifth of the 5.0 MHz error indicated on the oscillator cover $\pm 1$ count. For example, for an oscillator Freq at $27^{\circ} \mathrm{C}$ of $5.0 \mathrm{MHz}+1.0 \mathrm{~Hz}$, a count of 1000.0000 kHz minus $0.2 \mathrm{~Hz} \pm 1$ count ( $999.9998 \mathrm{kHz} \pm 1$ count) should be obtained. If the $5.0-\mathrm{MHz}$ error were $-1.0 \mathrm{~Hz}, 0.2$ Hz would be added to the count $\{1000.0002 \mathrm{kHz} \pm 1$ count).
i. ADJUST-Crystal oscillator frequency adjustment for a displayed count as given in part $h$ of this step. To gain access to the oscillator frequency adjustment, remove the screw in the oscillator cover. The adjustment is made with the tuning tool.
j. Disconnect all test equipment.
k. Remove the 7D14 from the plug-in extender. Replace the left side shield on the unit.

## OUTPUT SIGNAL ADJUSTMENT

## Equipment Required

1. Indicator Oscilloscope
2. Amplifier plug-in unit
3. Time-base plug-in unit
4. Medium-frequency constant-amplitude sine-wave generator
5. Five-nanosecond GR cable
6. 50 -ohm in-line termination
7. GR to BNC male adapter
8. Three-inch screwdriver

## Control Settings

Set the controls as given under Preliminary Control Settings.

The location of the Output Signal adjustment is shown in Fig. 5-4.

## 7. Adjust Trigger Indicator Display Positioning

a. Install the 7D14 in the left vertical plug-in compartment of the Indicator Oscilloscope.
b. Remove the left side cover from the indicator Oscilloscope.
c. Set the amplifier unit for a vertical deflection factor of $50 \mathrm{mV} /$ division and the time-base unit for a sweep rate of $10 \mu \mathrm{~s} /$ division.
d. Connect the medium-frequency constant-amplitude sine-wave generator to the amplifier unit input through the five-nanosecond GR cable and 50 -ohm in-line termination.
e. Set the medium-frequency generator for a threedivision display ( 150 millivolts) at the 50 -kilohertz reference frequency.
f. Disconnect the generator from the amplifier unit input.
g. Connect the medium-frequency generator to the CH A INPUT through the five-nanosecond GR cable and GR to BNC male adapter.
h. Change the following control settings:

## Indicator Oscilloscope

| Vertical Mode | Left |
| :--- | :--- |
| A Trigger Source | Left Vert |

i. CHECK-CRT display; the Trigger Indicator squarewave display should be positioned in the CRT viewing area.
j. ADJUST-Display Positioning adjustment R866 to vertically position the Trigger Indicator display in the desired area of the CRT.

This completes the Adjustment procedure of the 7D14. Disconnect all test equipment. Replace the left side cover on the Indicator Oscilloscope.

## PARTS ORDERING INFORMATION

Replacement parts are available from or through your local Tektronix, Inc. Field Office or representative.

Changes to Tektronix instruments are sometimes made to accommodate improved components as they become available, and to give you the benefit of the latest circuit improvements developed in our engineering department. It is therefore important, when ordering parts, to include the following information in your order: Part number, instrument type or number, serial or model number, and modification number if applicable.

If a part you have ordered has been replaced with a new or improved part, your local Tektronix, Inc. Field Office or representative will contact you concerning any change in part number.

## SPECIAL NOTES AND SYMBOLS

| $\times 000$ | Part first added at this serial number |
| ---: | :--- |
| $00 \times$ | Part removed after this serial number |
| $* 000-0000-00$ | Asterisk preceding Tektronix Part Number indicates manufactured by <br> or for Tektronix, Inc., or reworked or checked components. |
| Use 000-0000-00 | Part number indicated is direct replacement. |

## SECTION 7

## DIAGRAMS AND CIRCUIT BOARD ILLUSTRATIONS

## Symbols and Reference Designators

Electrical components shown on the diagrams are in the following units unless noted otherwise:

$$
\begin{aligned}
\text { Capacitors }= & \text { Values one or greater are in picofarads }(\mathrm{pF}) . \\
& \begin{array}{l}
\text { Values less than one are in microfarads }(\mu \mathrm{F}) .
\end{array} \\
\text { Resistors }= & \text { Ohms }(\Omega)
\end{aligned}
$$

Symbols used on the diagrams are based on USA Standard Y32.2-1967.
Logic symbology is based on MIL-STD-806B in terms of positive logic. Logic symbols depict the logic function performed and may differ from the manufacturer's data.

The following special symbols are used on the diagrams:

The following prefix letters are used as reference designators to identify components or assemblies on the diagrams.

| A | Assembly, separable or repairable (circuit board, etc.) | LR | Inductor/resistor combination |
| :--- | :--- | :--- | :--- |
| AT | Attenuator, fixed or variable | M | Meter |
| B | Motor | Q | Transistor or silicon-controlled rectifier |
| BT | Battery | P | Connector, movable portion |
| C | Capacitor, fixed or variable | R | Resistor, fixed or variable |
| CR | Diode, signal or rectifier | RT | Thermistor |
| DL | Delay line | S | Switch |
| DS | Indicating device (lamp) | T | Transformer |
| F | Fuse | TP | Test point |
| FL | Filter | U | Assembly, inseparable or non-repairable (integrated |
| H | Heat dissipating device (heat sink, heat radiator, etc.) |  | circuit, etc.) |
| HR | Heater | V | Electron tube |
| J | Connector, stationary portion | VR | Voltage regulator (zener diode, etc.) |
| K | Relay | Y | Crystal |
| L | Inductor, fixed or variable |  |  |

## VOLTAGE AND WAVEFORM TEST CONDITIONS

Typical voltage measurements were obtained under the following conditions unless noted otherwise on the individual diagrams:

## Voltmeter

Type
Input Impedance
Range
Recommended type (as used for voltages on diagrams)

Non-loading digital multimeter
$10 \mathrm{M} \Omega$ on all ranges
0 to 1000 volts
Tektronix 7D13 Digital Multimeter

## 7D14 (B horizontal compartment)

| MEASUREMENT INTERVAL | See Waveform <br> note on each | BW | 5 MHz |
| :--- | :--- | :--- | :--- |
|  | COUPLING | diagram | DISPLAY TIME |

No signal input for voltage measurements. $4 \mathrm{~V}, 1 \mathrm{kHz}$ square wave from oscilloscope Calibrator applied to CH A INPUT connector for waveforms.

7A16 (right vertical compartment using a 10X probe with readout coding ring. P6053 probe used for waveforms on diagrams)

| Polarity | +UP |
| :--- | :--- |
| Bandwidth | Full |
| Position | Centered |
| Coupling | AC |
| Variable | Cal In |
|  | $\mathbf{7 B 5 0}$ (A horizontal compartment) |
| Level/Slope | Centered on positive slope |
| Triggering |  |
| Mode | Norm |
| Coupling | AC |
| Source | Ext $\div 10$ |
| Magnifier | X1 |
| Variable | Cal In |
| Ext Trig In connector | No connection for voltage measurements. |
|  | For waveforms, see waveform note on |
|  | each Diagram. |
|  | 7704 |
| Vertical Mode | Right |
| Horizontal Mode | A |
| A Intensity | Optimum |
| B Intensity | Counterclockwise |
| Calibrator |  |
| Volts | 40 mV |
| Rate | DC |
| A Trigger Source | Right Vert |

Waveforms shown are actual waveform photographs taken with a Tektronix Oscilloscope Camera System and Projected Graticule. Vertical deflection factor shown on waveform is the actual deflection factor from the probe tip. Voltages and waveforms on the diagrams (shown in blue) are not absolute and may vary between instruments because of component tolerances, internal calibration, or front-panel settings. Readouts are simulated in larger-than-normal type.

## NOTE

The spring tension of the pin sockets ensures a good connection between the circuit board and pin. This spring tension may be damaged by using the pin sockets as a connecting point for spring-loaded probe tips, alligator clips, etc.

## FIGURE AND INDEX NUMBERS

Items in this section are referenced by figure and index numbers to the illustrations which appear either on the back of the diagrams or on pullout pages immediately following the diagrams of the instruction manual.

## INDENTATION SYSTEM

This mechanical parts list is indented to indicate item relationships. Following is an example of the indentation system used in the Description column.

```
Assembly and/or Component
    Detail Part of Assembly and/or Component
    mounting hardware for Detail Part
        Parts of Detail Part
        mounting hardware for Parts of Detail Part
mounting hardware for Assembly and/or Component
```

Mounting hardware always appears in the same indentation as the item it mounts, while the detail parts are indented to the right. Indented items are part of, and included with, the next higher indentation.

Mounting hardware must be purchased separately, unless otherwise specified.

## PARTS ORDERING INFORMATION

Replacement parts are available from or through your local Tektronix, Inc. Field Office or representative.

Changes to Tektronix instruments are sometimes made to accommodate improved components as they become available, and to give you the benefit of the latest circuit improvements developed in our engineering department. It is therefore important, when ordering parts, to include the following information in your order: Part number, instrument type or number, serial or model number, and modification number if applicable.

If a part you have ordered has been replaced with a new or improved part, your local Tektronix, Inc. Field Office or representative will contact you concerning any change in part number.

Change information, if any, is located at the rear of this manual.

## ABBREVIATIONS AND SYMBOLS

For an explanation of the abbreviations and symbols used in this section, please refer to the page immediately preceding the Electrical Parts List in this instruction manual.

## MANUAL CHANGE INFORMATION

At Tektronix, we continually strive to keep up with latest electronic developments by adding circuit and component improvements to our instruments as soon as they are developed and tested.

Sometimes, due to printing and shipping requirements, we can't get these changes immediately into printed manuals. Hence, your manual may contain new change information on following pages.
A single change may affect several sections. Sections of the manual are often printed at different times, so some of the information on the change pages may already be in your manual. Since the change information sheets are carried in the manual until ALL changes are permanently entered, some duplication may occur. If no such change pages appear in this section, your manual is correct as printed.

ELECTRICAL PARTS LIST AND SCHEMATIC CORRECTION A1 HIGH FREQ COUNTER Circuit Board Assembly

CHANGE TO:

| Q364 | 151-0367-00 | Silicon | NPN | SKA6516 |
| :--- | :--- | :--- | :--- | :--- |
| Q376 | $151-0367-00$ | Silicon | NPN | SKA6516 |
| Q384 | $151-0367-00$ | Silicon | NPN | SKA6516 |
| Q392 | $151-0367-00$ | Silicon | NPN | SKA6516 |
| Q402 | $151-0367-00$ | Silicon | NPN | SKA6516 |
| R332 | $315-0132-00$ | $1.3 \mathrm{k} \Omega$ | $1 / 4 \mathrm{~W}$ | $5 \%$ |

ADD:

| L364 | $276-0569-00$ | Core, toroid ferrite |
| :--- | :--- | :--- |
| L376 | $276-0569-00$ | Core, toroid ferrite |
| L384 | $276-0569-00$ | Core, toroid ferrite |
| L392 | $276-0569-00$ | Core, toroid ferrite |
| L402 | $276-0569-00$ | Core, toroid ferrite |

Add a toroid core in series with base lead of each transistor.

[^0]:    ${ }^{1}$ If the maximum frequency is exceeded, a "greater than" symbol $(>)$ will precede the readout display.

[^1]:    ${ }^{1}$ Used only for Pertormance Check procedure.
    ${ }^{2}$ Used only for Adjustment procedure,

[^2]:    d. Set the amplifier unit for a vertical deflection factor of $\mathbf{2 0}$ millivolts/division.

[^3]:    e. Set the pulse generator variable period control for a seven-division pulse period.

[^4]:    Quad 2 -input NOR gate. Replaceable by T.I. SN7402N
    Quad 2 -input NOR gate. Replaceable by T.I. SN7402N
    Triple 3 -input gate. Replaceable by T.I. SN7410N
    Triple 3 -input gate. Replaceable by T.I. SN7410N
    Quad 2 -input NOR gate. Replaceable by T.I. SN7402N
